SIRS,—Will you allow me to add a note to the letter which appeared in your issue of March 9th, p 736? In the list there given the section of anthropology is not mentioned Scattered among papers of purely medical importance, however, appears a considerable number of articles bearing on anthropological questions which it will be only too easy to overlook, especially if the journals or books are not readily accessible May I ask authors to send separate copies of their publications, or in default of that, a note of place and date of publication and of the main contents of the paper, to the Anthropological Institute, 3, Hanover-square, London, W.

I am, Sirs, yours faithfully,
Hanover-square, W. NORTHCOTE W. THOMAS.

"THE X RAYS IN SOUTH AFRICA."

To the Editors of THE LANCET.

SIRS,—In a letter on this subject which you were good enough to publish in THE LANCET of Jan. 19th last, p 212, I stated that the apparatus sent out by the War Office for use in the military hospitals in South Africa was that known as the "army pattern made by Apps and Newton." Mr. Harry W. Cox, of Cursitor-street, London, E.C., by order from the War Office, sent out three sets of apparatus of his own manufacture and has asked me to correct my former statement to this effect. This request, if you will grant me space to do so, I shall be glad of an opportunity of complying with.

I am, Sirs, yours faithfully,
W. F. STEVENSON, Colonel, R.A.M.C.
Netley, April 22nd, 1901

"THE STATISTICS OF GASTRIC ULCER, WITH SPECIAL REFERENCE TO GASTRIC HÆMORRHAGE, ITS FREQUENCY AND FATALITY."

To the Editors of THE LANCET.

SIRS,—I hardly think I need add anything to my letter in THE LANCET of March 30th, p. 969. Let me, however, thank Mr. Mayo Robson for the references which he has published, and let me say that those references entirely confirm my statement—viz., that the mortality percentages from hæmorrhage in gastric ulcer, given by the authorities which Mr. Mayo Robson quoted in his address, refer not merely to those cases of gastric ulcer in which hæmorrhage occurs, but to *all* cases of gastric ulcer.

Let me further say that, so far as I see, it is impossible to reconcile the estimate which Mr. Mayo Robson has drawn from those figures—viz., that 7 per cent of cases of hæmatemesis from ulcer, or 3½ per cent. of all persons suffering from ulcer, die as the result of bleeding—with those figures—viz., Muller, 11 per cent.; Welch, 3 to 5 per cent.; Brinton, 5 per cent.; Debove, 5 per cent.; Steiner, 6 36 per cent.; Lebert, 3 per cent; Dreschfeld, 3½ per cent.; and Rodman, 8 per cent.—unless, first, it be granted (and this is, as I have shown, an erroneous reading of the figures) that those figures refer to the mortality percentages in those cases of gastric ulcer in which hæmorrhage occurs (which Mr. Mayo Robson estimates at 50 per cent.); and, secondly, unless the mean (7 per cent.) of the extremes (11 per cent and 3 per cent), and not the average, of those figures is taken. The average of the figures is just about 5½ per cent. Let me also add that the mortality percentages of Lebert and Leube (Rodman), which Mr. Mayo Robson quotes, do not, according to my reading, represent the figures of those authorities (see *addendum*).

I hope one result of this discussion will be finally to "knock out of time" Brinton's estimate—that the total mortality in cases of gastric ulcer is 50 per cent. It does not seem to have occurred to Mr. Mayo Robson that he has taken up a singularly illogical, and, in fact, untenable, position in upholding Brinton, while, at the same time, he "heartily concurs" with my argument that, since the cicatrices of small and superficial ulcers are often missed, the ratio of three cicatrices to one open ulcer (which is the ratio commonly accepted by modern authorities) is probably an under estimate Brinton's estimate is essentially based on the supposition (which Brinton believed to be a fact) that the ratio of cicatrices to open ulcers is as one to one Hence he (Brinton) concluded that only 50 per cent. of gastric ulcers undergo a spontaneous cure; in other words, that the total mortality (direct and indirect) in cases of gastric ulcer is 50 per cent Now, if it be granted that the ratio of cicatrices to open ulcers is at least three to one, it necessarily follows that Brinton's estimate is extravagantly erroneous.

I have no wish to prolong the discussion, which, though of very great practical importance (since the statistics of gastric ulcer necessarily form one of the factors on which physicians and surgeons will have to determine the operative question), is, after all, merely preliminary to the main question—viz, whether operative interference is advisable for the treatment of hæmorrhage in cases of gastric ulcer, and, if so, in what cases it should be undertaken *On this, the main question, I have a good deal more to say*

I am, Sirs, yours faithfully,

Edinburgh, April 18th, 1901 BYROM BRAMWELL

ADDENDUM.

[illegible] from hæmor- [illegible] "In 120 [illegible] 14 were [illegible] gastric ulcer [illegible] incorrectly—[illegible] ulcers and 37 cases of hæmorrhage, instead of 120 ulcers and 35 cases of hæmorrhage, and Mr Mayo Robson quotes Savariaud)

Welch, from 3 to 5 per cent (Pepper's System of Medicine, vol. ii., p. 602) —"Death from hæmorrhage occurs probably in from 3 to 5 per cent. of the cases of gastric ulcer In 270 cases of open ulcer from the statistics of Jaksch, Dittrich, Eppinger, Starcke, Chambers, Habershon, Moore, and Lebert, I find 27 deaths by hæmorrhage. Reckoning three cicatrices to one ulcer this would give a percentage of 3½"

Brinton, 5 per cent. (Diseases of the Stomach, p. 153).—"In 3 5 per cent. of the cases of gastric ulcer death is due to hæmorrhage.'

Debove, 6 per cent. (Ulcère de l'Estomac, p. 101)—Debove and Renault give no estimate of their own, but merely quote Brinton's estimate, giving it at 5 per cent. and not, as Brinton gives it, at 3 to 5 per cent

Steiner, 6 36 per cent.—There is, so far as I see, no mention of the mortality from hæmorrhage in the abstract of Steiner's pathological observations in Virchow and Hirsch's Jahresbericht, 1863 p 125—the reference which Mr Mayo Robson gives The mortality is given in Steiner's Dissertation, "Das Chronische Corrosive Magengeschwür." Berlin, 1868 (I have not been able to consult the original) quoted (as Mr Mayo Robson points out) by Leube in Ziemssen's Cyclopædia, vol vii., p 217: "In 110 cases of gastric ulcer fatal hæmorrhage occurred in seven"; giving a mortality of 6 36 per cent. in all ulcers

Lebert, 3 per cent. (Die Krankheiten des Magens, 1878, pp. 237 and 238).—If I read Lebert rightly, he does not make the mortality from hæmorrhage 3 per cent., but 1 3 per cent. He observed 300 cases of gastric ulcer—252 in the clinics and polyclinics of Zürich and Breslau, and 48 in the Paris hospitals and in private practice. Of these 300 cases of gastric ulcer 33 or 11 per cent., died, and of the 33 fatal cases four, or *1·3 per cent, of the 300 cases of ulcer died from hæmorrhage.* Mr Mayo Robson is, I think, mistaken in saying that Lebert's figures on this point (the mortality from hæmorrhage) are quoted by Dreschfeld in Clifford Allbutt's System of Medicine, vol. iii, p. 541 They are, however, quoted—and I think, erroneously quoted—by Savariaud (L'Ulcère Hémorrhagique de l Estomac, 1898, p 51) as follows: "Lebert, who observed 252 cases, found 3 per cent. died from hæmorrhage." Lebert's statement, according to my reading, is given above.

Dreschfeld. 3½ per cent. (Clifford Allbutt's System of Medicine, vol. iii., p. 541) —"Death from hæmorrhage is said to occur in about 3 per cent."

Rodman, 8 per cent. (Journal of the American Association, June 16th, 1900, p 1509) —"Hæmatemesis occurs in at least 50 per cent. of all cases of gastric ulcer, and many authorities estimate it as present in 80 per cent. It is, too, fatal in 8 per cent. of the cases in which it occurs, according to the conservative estimate of Leube (*Archiv für Klinische Chirurgie*, 1897), and we cannot question that it is indirectly fatal in a much greater number of cases by anæmia and its remote consequences."

Rodman seems to have misread Leube, for, according to my reading, Leube's 8 per cent. refers *not* to the fatality of hæmorrhage in gastric ulcer, but to the *total* fatality of gastric ulcer Leube (*Archiv für Klinische Chirurgie*, 1897, p 73) says: "Ich habe berechnet, *dass von* 195 Patienten, die vor oder *nach der Behandlung* Magenblutungen *zeigten 8*, also etwas über 4 per cent. mit Tod abgingen, während nach den gewöhnlichen Rechnungen die Mortalitätszahl beim Ulcus 13 per cent. und noch mehr beträgt." Or, as I translate it: "I have calculated that in 195 patients in whom bleeding from the stomach occurred, either before or after treatment, eight, or about 4 per cent., died, whereas according to the usually accepted estimates, the mortality *from* gastric ulcer is 13 per cent. or more." Leube then goes on to give the details of his own cases He observed 656 cases 63 in private practice and 493 in hospital practice. Of these 656 cases of gastric ulcer 12 died, making the total mortality 2 15 per cent, and of the 12 fatal cases six died from hæmorrhage, *giving a mortality from hæmorrhage of 1 per cent.* He contrasts his total mortality of 2 15 per cent, and his mortality from hæmorrhage of 1 per cent., with the usually accepted estimates, based on old and recent statistics, which give the total mortality from gastric ulcer at 13 per cent or more and [illegible] Thus, according to my [illegible] ees Mr Mayo Robson [illegible] f it were Rodman's [illegible] of the way in which [illegible] ric ulcer are quoted, requoted, and misquoted

---

[1] The figure which immediately follows the author's name (Müller, Welch &c.) is Mr Mayo Robson's quotation

"NEUTRAL RED AS A MEANS OF DETECTING THE PRESENCE OF THE BACILLUS COLI COMMUNIS IN WATER-SUPPLIES."

To the Editors of THE LANCET.

SIRS,—A note bearing the above title was published in THE LANCET of April 13th, p 1079, and as I was out of London during the week previous to the insertion of this note I did not have an opportunity of correcting the proof which was submitted to me As one or two points appear to me to be far from clear the following may be useful. Nutrient media, especially peptone bouillon, containing neutral red, form a delicate test for the presence of bacillus coli communis Thus one cubic centimetre of unsterilised tap water containing from 10 to 20 bacilli coli per cubic centimetre, mixed with neutral red bouillon and incubated at 37° C, will give a marked reaction within 24 hours If, however, the bacilli only number from three to four per cubic centimetre the reaction is usually delayed until the second day. By noting such differences in the time required to produce the reaction a fairly accurate idea of the proportions of bacillus coli communis present in a water can be gained. Dr. Makgill (late of New Zealand) has been making a number of experiments in regard to this question and intends to publish soon the results of his investigations more in detail.

I am, Sirs, yours faithfully,

London Hospital, E., April 17th, 1901 WILLIAM HUNTER

WIDE-BORE CLOVER'S INHALERS.

To the Editors of THE LANCET.

SIRS,—In Dr. Frederic Hewitt's lecture published in THE LANCET of March 30th, p 916, I am interested to see an account of an improved Clover's ether inhaler with a wide bore or calibre, and also that Dr Hewitt finds that the "principal difference" thereof "is that stertor and cyanosis are lessened and that the patient passes smoothly with little or no respiratory derangement from the anæsthesia of nitrous oxide to that of ether" Dr. Hewitt states that he has used this apparatus for upwards of a year in private practice.

In April, 1898, you published a description of an improved Clover's inhaler designed by me and made by Messrs. Mayer and Meltzer At the same time, by my instructions, Messrs Mayer and Meltzer made for me a *wide bore* Clover's inhaler on the same principles save for the introduction of the wider bore I have used this wide bore inhaler exclusively since February, 1898, with every satisfaction, and from three years' experience can fully endorse Dr. Hewitt's remarks as to the quietness of breathing and ease with which patients pass from gas to ether anæsthesia The difference in ease of breathing with the wide- and narrow-bore Clover's inhalers respectively is strikingly demonstrated by breathing through one and then immediately substituting the other

I have no doubt that Dr Hewitt's explanation that with the narrow bore inhalers a negative pressure is produced within the upper air-tract is the correct one There is also a corresponding, though reversed, feeling of effort during expiration with the narrow-bore inhalers I think that the late Mr. Clover, notwithstanding his ingenuity, must have forgotten in designing his smaller inhaler that the central tube, roughly about the area in section of the human trachea, has only half this area available for respiration, by reason of the dividing septum Any inhaler on Clover's pattern, to allow of full ease in respiration must be made with a central tube of an area in section equal to double that of the trachea, thus allowing for an area, in section equal to that of the trachea, on each side of the septum dividing the central tube. It was on this principle that I designed my wide-bore improved Clover's inhaler more than three years ago.

I am, Sirs, yours faithfully,
Bath, April 16th. T. WILSON SMITH, M.D. Lond.

"A WATER COMPANY DIRECTOR ON CISTERNS."

To the Editors of THE LANCET.

SIRS,—I thank you for your courtesy in sending me THE LANCET of 20th inst. with the note on the *Times* report of my remarks at the general meeting of the East London Waterworks Company, necessarily much condensed. I had in view the statements made to me by Mr. H. Mansfield Robinson at one of the sittings of the Local Government Board inquiry on the proposed regulations as to the dirty state of many cisterns in the poorer parts of Shoreditch and the contaminations discovered in them. Where this is the case I think you will support the view that if the authorities are powerless to insist on proper cisterns and their being cleansed the water for drinking purposes should be drawn from a tap on the rising main.

The suffering unhappily experienced in East London during the drought was mainly due to insufficient supply for cleansing and general purposes and would have been greatly mitigated had there been even a small cistern in every house.

I am, Sirs, yours faithfully,
Tunbridge Wells, April 21st, 1901. F. TENDRON.

"THE TRAFFIC IN OLD HORSES."

To the Editors of THE LANCET.

SIRS,—I have read in your issue of April 13th, p. 1095, an annotation entitled "The Traffic in Old Horses," in the course of which the writer observes: "We have not, however, seen reported a single case where punishment has been inflicted under the Diseases of Animals Act and the Order of the Board of Agriculture, and we should be glad to know why magistrates and others do not use the powers to which they are entitled." Allow me to point out that the first two lines of your annotation furnish the answer to your inquiry. Our officers not being allowed on the wharves stop the horses *en route* to the docks, and, as you have shown, obtain convictions for travelling such horses when lame or unfit—convictions occurring almost daily; thus the action of the society prevents the cruelty of transporting such animals to continental cities.

I am, Sirs, yours faithfully,
JOHN COLAM,
Secretary to the Royal Society for the Prevention of Cruelty to Animals.
Jermyn street, S W., April 17th, 1901.

CIVIL SURGEONS IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—A desire has been generally expressed by men recently serving as civil surgeons in South Africa to hold a dinner. Derby Day, Wednesday, June 5th, the anniversary of the occupation of Pretoria, is suggested for the purpose. It is proposed to include all civilian medical men, whether attached to the Royal Army Medical Corps or to private hospitals. Sir W MacCormac has consented to preside and the following surgeons have already expressed their intention of being present: Mr. Makins, Professor Chiene, Mr. Watson Cheyne, Mr. Fripp, and Sir William Thomson.

The following provisional committee has been formed:—Mr. Anthony A. Bowloy (chairman of committee), Mr. C. S. Wallace (St. Thomas's), Dr. E A. Houseman (St. George's), Dr. A. Conan Doyle (Edinburgh), Dr. J. F. R. Gairdner (Glasgow and Leeds), and Mr. E. L. Hunt (Dublin).

We shall be glad to receive suggestions at the address given below, and we hope to publish details at a later date.

We remain, Sirs, yours faithfully,
C. GORDON WATSON (St. Bart.'s),
FRANCIS E. FREMANTLE (Guy's),
Acting Secretaries.
39, Moore-street, Lennox-gardens, S W.

"BICYCLING IN LONDON."

To the Editors of THE LANCET.

SIRS,—As a lady cyclist who is accustomed to ride in almost every part of the metropolis I cannot refrain from protesting against what appears to me the somewhat exaggerated view of the dangers of bicycling in London expressed in an annotation on that subject in THE LANCET of April 20th, p. 1154. Contrary to the opinion of the author of that article I find that one of the great advantages of bicycling in London is the freedom from nerve wear and tear it affords as compared with some other methods of locomotion. One avoids the worry of catching or missing omnibuses and trains, the irritation often produced by the dilatory progress of these means of transport, the anxiety that one will be late for one's appointment. Driving in a hansom is, in my experience, frequently a succession of small nerve shocks. What with curbstones which are grazed, absent-minded pedestrians who appear to escape as by a miracle being run over, horses that flounder and threaten to fall, one's nerves are often kept in a state of tension from which the practised cyclist is wholly free. When cycling the speed is in one's own hands. What one loses in crowded roads can be made up for in quieter parts One feels absolute control over one's machine, a control more complete and more rapidly exercised than that over any horse. There is enough muscular exertion to produce a feeling of pleasant exhilaration; just enough skill and alertness are called for to give brain and eye healthy exercise.

Whether bicycling in London is dangerous or not depends very largely on the cyclist. The crowded thoroughfares of the metropolis are far from being a sort of pandemonium, as suggested by the article referred to; the traffic is perfectly regulated, every horse is well under control. So long as the cyclist keeps his place he is no source of danger either to himself or others. The cyclist who courts danger and annoys drivers is he who presumes on the superior agility and speed of his machine as compared with other vehicles and darts through the traffic, dodging horses' heads on one side and shaving wheels on the other. It is often said that ladies are among the most reckless riders in London streets, but this, I think, is wholly untrue. Incompetent riders and nervous riders one sees, neither of whom are fit to cycle in crowded thoroughfares, but the foolhardy expert is almost invariably of the opposite sex. It often makes one shiver to watch cyclists, newspaper carriers especially, who dash through the traffic over greasy roads as if side slips were non-existent.

The best way, I think, for a lady to learn to ride safely in traffic is to make a point of dismounting and walking whenever the traffic or condition of the road makes her feel the least nervous. She will gradually find she dismounts less and less frequently and gains confidence while avoiding the chance of getting into tight places. Personally I feel far happier on a bicycle at certain crossings—Trafalgar-square, for instance—than I do on my feet. I do not advocate riding in muddy weather, but I believe that it is far more possible than is generally supposed for the cautious rider to ride safely on greasy roads if he bears constantly in mind the possibility of a side slip and acts accordingly.

I am, Sirs, yours faithfully,
April 22nd, 1901. M.D. LOND.

⁂ "At about 9.45 this morning a young lady, who was cycling along the Holloway-road, slipped, and an omnibus following passed over her. She was removed to the Great Northern Hospital, but expired before arrival."—(*Evening Standard*, Tuesday, April 23rd, 1901)—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Water-supply of Bombay City and other Indian Cities—The Utilisation of Garbage by Municipalities—Features of the present Plague Mortality.—The Distribution of Prizes by the Gaekwar of Baroda.

THE water-supply of Bombay city from the Tausa, Vehar, and Tulsi lakes has justly been a matter of pride to the municipality for many years and I am glad to see by a recent analysis by one of the health officers that it maintains its purity. It will be remembered that last year during the autumn some suspicion was cast on the water supply and vibrios in abundance were found in the water. At the same time a marked increase in the albuminoid ammonia was discoverable which was attributed to algoid growth The following, however, is the recent analysis:—

Tausa Water.—Total solids, 8 grains per gallon; chlorine, 0·3 grain

[illegible] 0·002 part per 1,000,000 [illegible]minoid, 0 09
[illegible] 1 2 grains
[illegible]oid, 0 0[illegible]
[illegible] 1 2 grains
[illegible]inoid, 0·072

The available daily supply is very large. A recent return shows that Allahabad uses about 1,500,000 gallons a day at a cost of one and a half annas per 1000 gallons, Agra about the same daily supply at one and seven-twelfth annas per 1000 gallons, Lucknow rather more than 1,000,000 gallons at two and one-twelfth annas, and Benares two and two-third million gallons a day at two and one-third annas. Meerut uses well water which is very expensive, and Mussoorie has a notoriously inadequate supply. Attention has already been drawn to the increasing death rate of these cities and the census returns show but a small increase in the population.

The conservancy of Calcutta has always been a matter of difficulty as the amount of refuse to be carted away daily is enormous. The greater part is taken outside the town and deposited in what is known as the "salt lakes," but a portion has been burnt in two Harrington incinerators. It is contemplated to establish more of these works as they will effect a considerable saving on the annual cost of removing garbage. The inventor claims that a boiler attached to this incinerator would maintain sufficient steam to work the machinery for lighting Calcutta with electricity.

Notwithstanding the thousands of cases of plague which have occurred in Calcutta I understand that there has been only one victim amongst Europeans. This was Major Evans, I.M S., who was thought to have contracted the disease while making a post-mortem examination. This week the house surgeon of the Ezra Hospital has died from plague; he was a native of India. The plague mortality throughout India is still enormous, although there has been a slight decline during the past week from 11,509 to 11,480 In the corresponding week last year the plague deaths numbered 5196 The disease for the moment is stationary in the Bengal districts and in Calcutta, and there is a decrease in the Bombay Presidency. In Benares city, however, the outbreak has become severe and over 100 deaths have been recorded in one day. It is still raging in Karachi and the total of cases and deaths in that city since Jan. 26th gives the mortality at 75 per cent In Calcutta the total of cases and deaths since Jan 1st gives a mortality of 84 per cent. As the excess mortality of the city is nearly all accounted for by the plague deaths it probably means that a large number of non-fatal cases do not come before the authorities. At the present time about 1000 deaths from plague are occurring each week in Calcutta, but there appears to be some sign of the plague mortality decreasing. A coincident minor outbreak of small-pox has been existent which has helped to swell the lists of general mortality. In Bombay city the outbreak is declining, but 705 deaths from plague were registered last week. The general mortality was 1716 against 1949 in the previous week—a rate of over 115 per 1000 per annum. The excess mortality is apparently due to plague because there is no other fatal epidemic disease present.

The Grant Medical College, Bombay, was fortunate in obtaining the presence of the Gaekwar of Baroda at the recent distribution of prizes. The Indian prince made a very excellent speech and referred to the advantages of a university education, the march of science, particularly with regard to medicine, the need of India for scientific education, and the importance of hygiene. He also touched upon the desirability of investigating Indian medicines and upon medical colleges in India. His Highness was very enthusiastically received and his address will doubtless prove of great value to the college. It was, however, more than an appeal to students, it was a valuable lesson to the whole native population of India. The stimulus of such an address must be far reaching, not only from its intrinsic merits, but from the great influence which the Prince possesses.

April 6th.

HEALTH OF KEYNSHAM.—Mr. J. O. Heaven in his annual report as medical officer of health of the Keynsham Rural District states that the estimated population in 1900 was 7542. The death-rate, including the deaths of 10 visitors, corresponded to a rate of 15 9 per 1000. The birth-rate was 25 3 per 1000

THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE British medical press will receive at an early date an invitation to appoint delegates so as to discuss and to draw up the statutes that are to govern the International Association of the Medical Press. It will be remembered that an International Congress, the first of its kind, was held from July 26th to July 28th, 1900, at Paris, during the Universal Exhibition. More than 200 representatives of medical journals were members of that Congress and the majority of the civilised countries of the world thus participated in the gathering. Many subjects were discussed, but the thing was so new to the members that very few practical decisions were taken. The main result was a unanimous agreement that an international association of the medical press should be established. It was felt, however, that it would be premature to define with any precision the object and rules of such an association. The Congress decided that the committee which had organised the Congress should be empowered to draw up a scheme of rules, and it is this scheme that will shortly be issued to the various countries which were represented at the Congress. In the meanwhile, efforts were to be made in the various countries to group the medical journals and thus to constitute national associations of the medical press that could express an opinion on the scheme. So far nothing of the sort has been attempted in Great Britain. Each national meeting will be called upon to appoint delegates to represent its views, and to move such alterations of the proposed rules as it may judge expedient at the next International Congress. It was decided last year in Paris that Germany and Austria should appoint four delegates, England, France, Italy, and the United States of America three delegates each, Spain and Russia two delegates each, and the other nationalities one delegate each. The next International Congress of the Medical Press will meet at Brussels on Sept. 20th of this year and all representatives of medical periodicals will be allowed to become members of the Congress. But the delegates mentioned above are to meet a day or two before the general Congress. They are then to submit their amendments to the draft of the rules and to come to a joint agreement as to the project of rules to be proposed to the Congress for definite adoption. This preliminary meeting of the delegates will be more important from a business point of view than will be the Congress itself. It must be acknowledged that every precaution has been taken to ensure that the rules shall be thoroughly international in character and in harmony with the opinions of the majority. The first scheme of rules, though drawn up by the French committee, will be based upon the discussions which were held last year and at which most nations participated, and each nation will separately be able to criticise and to suggest alterations of these rules. Then the delegates of these nations on meeting at Brussels will try to weld together their different suggestions, and finally the International Congress as a whole will confirm or alter this project. The members of the French committee are Professor V. Cornil, Professor Charles Richet, Dr. R. Blondel, Dr Laborde, Dr. Marcel Baudouin, and also Professor Posner of Berlin. It is these gentlemen who are to prepare the draft of rules which will soon be sent to all the nations concerned and which the medical press will be called upon to criticise, and subsequently to appoint delegates to convey their criticisms to the Brussels Congress. The secretary of this the forthcoming Second International Congress of the Medical Press is Dr. Pecherc, 140, rue de la Loi, Brussels, to whom all communications relating to the Congress should be addressed.

Thus the matter stands at present and the next question is, What action will be taken by the medical press of this country? The main difficulty arises from the very different character and position of the medical journals in various countries and even within the frontiers of any one particular nation. Yet, in spite of this, there may be some common ground of agreement. For instance, it is proposed to establish, on coöperative principles, a central international bureau of information. The editors of the various papers could send, probably in the French language, as being the language most widely understood, brief summaries of any important article they may publish which would be forwarded by the central bureau to all the papers belonging to the association. Thus each paper would receive for quotation press cuttings of what the editors of a great number of papers themselves thought was the most important matter published in their columns. This might not be considered very useful by papers which have regular correspondents in the principal capitals of Europe, but it would be of service even to such papers when the information came from smaller countries. In Denmark, Norway, Switzerland, and other small or distant countries much good work is done that remains ignored by the world at large because there is no regular system of correspondence and because, in many cases, the language spoken in these countries is scarcely known beyond their frontiers. Again, there is a great deal to be done in regard to the ethics of the medical press. First, it is necessary to define what is worthy to be called a medical journal and then what form of advertisements such papers may publish without compromising the honour and dignity of the medical press. Of course, ethical principles are difficult to define and still more difficult to enforce, but the most powerful means to this end is to create a wholesome public or professional opinion, and congresses very materially help in developing such opinion. Then there is the whole question of copyright and the limit up to which quotations are justifiable. The international assimilation of medical terms is also a very practical problem which an international association of the medical press might well help to solve. Thus it will be seen that there is no lack of useful work that could be undertaken, and in any case, and whatever may be the result, the British medical press should take its fair share of the efforts made by other nations for the common good.

Paris, April 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"How the Poor Die."

THIS is the heading in one of the Manchester papers to the report of an inquest held by Mr. J. F. Price, the county coroner, at Withington Workhouse on April 10th. A working cabinet-maker living in lodgings in Hulme had been ailing for some time and was occasionally intemperate. On April 1st he was taken ill at his work, and the next day a fellow lodger applied at the Chorlton Union offices, and the invalid was seen by a medical man who ordered his removal to the Withington Workhouse Hospital. About 7 P M. he was assisted into the ambulance van which was sent for him, but on its reaching the workhouse the man was not in it. A policeman met him staggering along Burton-road and, with the usual amount of diagnostic insight possessed by his class, thought he was drunk and told him to go home. The man, however, went into a hotel and on coming out fell down, whereupon he was taken to the police-station. He was visited, so it is stated, every hour, but made no complaint of illness till next morning, when he was removed to the workhouse hospital, where he died two days later. "Medical evidence described the cause of death as consumption and pneumonia." "Death from natural causes" was the verdict of the jury, "who suggested that an attendant should always accompany persons sent in the van to the workhouse." This very proper suggestion was met by the statement that it was not the practice except in cases of lunacy; but if a patient is so ill as to require to be taken in the ambulance to the workhouse he should be looked after and cared for on the journey. It is satisfactory to find that at a meeting of the guardians on April 12th the chairman "instructed the relieving officers to either accompany patients to the workhouse or send some other person with them." This unfortunate case cannot serve as an indication or an illustration of "how the poor die." It is sad enough; but the only exception—so far as the evidence went—to the proceedings of the Poor-law authorities that can fairly be taken is the fact that the *man* was sent alone in the ambulance. This should not have happened and will not happen in the future. The reporter presumably yielded to the temptation of using a sensational heading, even though, happily, this exceptional case does not tell us "how the poor die."

The Mauldeth Hospital Fund.

The Mauldeth Hospital is devoted to the care of incurable cases, and in aid of its funds an exhibition of art and handicrafts is being held in the Chorlton Town Hall, Manchester. One section is given over to "works of representative artists," chiefly sent for exhibition only. Another contains specimens of art work, crafts, and curios from many lands. Some of these are on sale. A third section is for "articles representative of British art and crafts sent in for competition." "The Canterbury Weavers" send an interesting sample of work. In Canterbury an attempt has been made and, it is said, successfully, to revive the old industry of hand-loom weaving. Employment is already given "to 30 or 40 girls, many of whom were physically incapable of ordinary hard work." The exhibition was opened on April 10th and is to remain open for a month, and the proceeds are to be devoted to one special branch of the work of the hospital—the provision of small pensions. The committee of the hospital give about £400 a year in pensions of £20 "for the benefit of afflicted persons who prefer to live with their relatives." Great care is taken in the selection of these cases. The exhibition was declared open by Sir W. H. Bailey, whose address was in the main a vindication of Manchester from the charge of being wholly given up to commercialism.

Vicissitude.

Exposed for sale in the shop window of a dealer in old plate and jewellery in Manchester is a richly-chased silver salver. In the centre an inscription is engraved which reads as follows: "Presented to —— Esq., M.R.C.S., L S A., as a token of gratitude and esteem by the widow and children of the late ——, surgeon, —— [the name of a neighbouring town], in whose last trying illness he not only displayed the skill of the physician, but the unvarying kindness and attention of a friend.—June, 1864." Not so very many years have passed since this token of loving kindness and grateful remembrance was given and received with painful pleasure and it may now perhaps go the way of old silver, be melted down and worked up again into a similar memorial of affection.

Hospital Sunday.

The committee of the Hospital Sunday Fund for Manchester announce that the total amount collected on Feb. 10th was £4062. This is an increase of £196 over last year's collection. Hospital Saturday is fixed this year for May 4th.

Manchester Port Sanitary Authority.

At the meeting of the Manchester Corporation Ship Canal Consultative Committee held on April 17th a letter from the Local Government Board was submitted in reference to establishing a permanent port sanitary authority for Manchester. The Board recommend that the authority shall consist of four representatives from Manchester, four from Salford, one from Stretford, one from Eccles and district, one from Warrington, one from the district of Runcorn, and one from the Widnes district, the costs to be divided proportionately. A public inquiry is to be held shortly as to the desirableness of these proposals. Although a close watch is kept to guard against the importation of plague or any other infectious disease it is very desirable that all the machinery for the purpose should be carefully arranged and kept in good working order.

Manchester and Salford Co-operative Society.

The Manchester and Salford Co-operative Society is composed almost entirely of those who are called the working-classes. There are, it is said, 14,572 members, who have standing to their credit in the society the sum of £210,829 They do a large business, the sales for the last quarter having amounted to £92,382. After all charges have been made a dividend of 2*s*. 3*d*. in the pound is given on members' purchases, and of 10*d*. in the pound on those of non members, various grants and bonuses are also given, and the following contributions to medical charities are made To the Children's Hospital, £5 5*s*.; to the Royal Albert Asylum, £5 5*s*.; to the Manchester Royal Infirmary, £10; and to the Northern Counties Hospital for Incurables, £5 5*s*.

Dr. Metchnikoff on Microbes and the Human Body.

A special meeting of the Manchester Literary and Philosophical Society was held in the Society's Library in George-street on April 22nd, when Dr. Elie Metchnikoff of the Pasteur Institute, Paris, delivered the "Wilde" Lecture.

Before its delivery, Professor Lamb, the President of the society, presented the Wilde Medal for 1901 to Dr. Metchnikoff, and the Wilde Premium to Mr. Thomas Thorp. The subject of the lecture, which was delivered in French, was "*La Flore Microcobienne du Corps Humain.*" There is no question as to the interesting nature of the lecture, though it might perhaps have been a little startling and disquieting to those of the audience who were not previously aware of the methods exhibited by nature in our bodily arrangements It seems that we are born free from microbes, but immediately after birth the surface of the skin and of the mucous membranes becomes inhabited by them. In the skin the capillary follicles are their favourite abode, while the moist mucous membranes are even more abundantly supplied than the skin. But the digestive organs exhibit them in the greatest abundance. More than 30 species inhabit the mouth. Though many bacteria cannot endure an acid environment the bacterial system of the human stomach is "pretty rich," 30 different species having already been distinguished. In the small intestine bacilli are the predominating form and in the large intestine they are joined by a great number of new kinds. The latter is inhabited by about 45 species of microbes. It begins to be invaded immediately after birth, even before any food has been taken The microbes of the skin cannot be shown to do us any special good, but the flora of the mouth may be of service. Wounds in the mouth heal sooner than do those upon the outer skin. And it is probable that the acids secreted by many bacteria in the small intestine prevent the development of certain other microbes which may impede digestion. "There was reason to believe that in some cases the germs of Asiatic cholera were rendered innocuous by the action of the microbes which they encountered in the intestines." It has been contended that microbes played an important part in digestion, but the general conclusion from the data available is that "for the normal action of the human digestion the presence of the intestinal microbe was by no means indispensable." As to the harm done by microbes, when the defensive forces of the body flag the bacteria of the skin begin to multiply and "to pour their noxious products into the tissues and the blood," so that serious boils and anthrax may occur. But the greatest harm is done in the stomach and intestines The gravity of the danger in cases of perforation of the intestines "is due to the inflammatory action of the microbes that escape into the peritoneum." It is probable that a great many of the toxic products of our intestinal flora have still to be ascertained, but there is reason to state that they play a considerable part in causing many and various maladies Dr. Metchnikoff then asked how we were to square the conviction that so many of the microbes usually found in the body are injurious with the Darwinian argument that if so they ought to have been eliminated by natural selection. To account for this he drew "attention to the fact that the very organs of the body which sustained this flora were themselves for the most part either useless or injurious to health and life." The capillary follicles of the skin, inhabited by microbes capable of producing more or less serious disease, "were useless organs and represented merely what was left of the hair that covered the skin of animals who were our ancestors" In the digestive apparatus of man there were parts, to say the least, now useless—e g, the vermiform appendix—"more fully developed in our animal forefathers," and already undergoing reduction in the anthropoid apes "Even the stomach . ... was in reality nothing but a large reservoir for food .. .. which could without serious inconvenience be dispensed with. There were at that moment four persons living without stomachs and thus furnishing a strong argument against the utility of that organ" Dr. Metchnikoff allowed that the small intestine was necessary, but that instead of being between 18 and 21 feet long man might do with one third of that length. Still more disrespectful was his attitude towards the large intestine. "The sum of all this was that we possessed a voluminous and highly-developed organ which fulfilled no useful function and bred a very copious and varied mass of microbes capable of injuring us through their poisons" Its development was traced to certain conditions in the life of herbivorous vertebrate animals capable of running at great speed, conditions no longer present, and so not requiring that special organisation. "The slow tendency of evolution to bring about the atrophy of such organs or characteristics might, however, be assisted by medicine and surgery, medicine coping more effectually with the noxious microbes and their effects, while the progress of surgery had already brought it within its power to remove by operation organs or parts of organs *propitious to the growth of the 'flora.'*" Dr. Schunck proposed and Professor Hickson seconded a vote of thanks to the lecturer which was accorded with acclamation.

April 23rd.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS)

Cardiff Infirmary.

ALTHOUGH, thanks to the energy and public spirit of the Mayor of Cardiff and of the proprietors of the *Western Mail* this institution is for the time cleared of its debt of £10,000, it is still unable to pay its way. With an expenditure of £2000 a year in excess of their income it was hardly likely that the Management Committee could entertain at their meeting on April 10th a proposal to open a disused ward of 15 beds, although the urgent necessity for the carrying out of the proposal was evident from the fact that no fewer than 143 patients were awaiting admission and some, it is said, had been waiting nearly nine months. The new operating theatre is to be opened on June 6th by Mr. Edmund Owen The donor of this much needed addition, which will cost about £1500, is Mr. Thomas Webb of the Ocean Colliery Company.

Vaccination in Cardiff.

Cardiff has hitherto been looked upon as a well-vaccinated town, but the inspections and investigations consequent upon the recent slight outbreak of small-pox have revealed conditions anything but satisfactory. In a report to the Health Committee at the end of March Dr. Edward Walford stated that in the street in which the first cases of small-pox occurred he found per 11 cent. of the children unvaccinated. On April 11th the subject was discussed by the Vaccination Committee of the Cardiff Board of Guardians, when it was reported that a Leicestershire railway contractor was carrying out extensive works in the town, that a large number of his workmen came from that county, and that it was their children in great measure who were unvaccinated. The chairman of the committee appeared to resent the interference of the Jenner Society from whom a communication had been received suggesting the purchase of the society's publications for distribution in the town. The committee considered that they were quite alive to their responsibilities and were doing all they could to enforce the Vaccination Act in spite of the fact that their attention was first drawn to the large number of unvaccinated children not by their own officers but by the medical officer of health.

The Medical Officer of Health of Newport.

The Local Government Act of 1888 required that every medical officer of health appointed after Jan. 1st, 1892, to an urban or rural district having a population exceeding 50,000 should possess special qualifications for the office, and it was confidently expected by those who took to public health work as a special line of practice that the Local Government Board would insist upon adequate remuneration being given at least to those who devoted their whole time to their duties That this expectation was not to be realised was only too apparent in numerous instances where the Board sanctioned appointments at salaries even below those paid to the chief inspectors of nuisances in some large towns. Lately, however, the Board have taken a firmer stand and have apparently decided that the minimum salary of a whole-time medical officer of health shall be £500 per annum and that where a contribution is made from the Exchequer grants an officer who is paid a smaller sum than this shall not be debarred from practising privately or from holding some other office. The Corporation of Newport—or, more strictly speaking, a small section of that body—have been endeavouring for the past six months to persuade the Board to sanction the renewal of the appointment of Dr. J. Howard-Jones at a salary of £400 as medical officer of health and of £50 as port medical officer. As the Board were proof against all persuasion the town council, at their meeting on April 9th, accepted the inevitable and reappointed Dr. Howard-Jones at an increased salary of £50 per annum as port medical officer. When it is remembered that Newport is an extensive port and has a population exceeding 70,000 persons, and that the medical officer of health also acts as police surgeon, a salary of £500 does not seem an exorbitant one and such indeed was the opinion expressed by the chairman of the Health Committee, who spoke in the highest terms of the capabilities of Dr. Howard-Jones and of the excellent work which he had accomplished during his six years of office.

Inefficient Vaccination.

At the meeting of the Bridgend Board of Guardians on April 13th it was decided to urge upon the Local Government Board the desirability of insisting that private practitioners should vaccinate as completely as public vaccinators are required to do. The opinion was expressed that children were sometimes insufficiently vaccinated by the private practitioner.

The Sale of Unsound Meat.

A case of some importance on appeal from a conviction by the Aberavon justices was heard at the Glamorgan Court of Quarter Sessions at Cardiff on April 13th. The borough of Neath and the urban district of Margam adjoin and almost form one town. In December last a butcher killed a pig in his slaughter-house in Neath and a farmer who had previously purchased it took the carcass to his own premises situated in Margam. The carcass was found to be unfit for human food, was condemned by the medical officer of health of Margam, and was ordered by a justice to be destroyed. At the instance of the Margam District Council the butcher was proceeded against before the county justices and he was fined £5. He appealed against this decision and at the quarter sessions his counsel contended that the proceedings ought to have been taken, not by the Margam District Council, but by the Corporation of Neath, in whose district the sale took place. The court held the contention to be a sound one and allowed the appeal, but consented, upon the application of counsel for the Margam sanitary authority, to state a case for the High Court.

Bequests to Charities.

Miss Selina Northcote of Woodbury has bequeathed £3000 to the Devon and Exeter Hospital, and £500 each to the West of England Eye Infirmary, Exeter, the Exeter Dispensary, and the West of England Asylum for Idiots.—Miss Mary Cannington, who died on March 30th, has bequeathed £5000 to the Bristol General Hospital, and £500 each to the Bristol Dispensary and the Bristol Eye Hospital. A few years ago Miss Cannington gave to the Bristol Royal Infirmary £10,000.

Hospital Sunday Fund in Bristol.

At a meeting of the council of this fund held on April 18th under the presidency of the Lord Mayor of Bristol, it was stated that the total collections for 1901 amounted to £1761, being an increase of £378 over the previous year. Collections were made in 246 places of worship, as compared with 223 last year. The total distribution to the medical charities amounted to £1713, as compared with £1313 in 1900.

April 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Glasgow.

THE movement of the epidemic continues to justify the favourable anticipations recently expressed by the authorities. The cases in hospital now number only 155 and the new admissions during the week have been fewer than for several months. At a recent meeting of the town council a member proposed that the daily bulletin should now be discontinued. The Lord Provost, in replying, referred to the unfortunate experience which followed this step when it was adopted in the earlier part of the year. At that time the epidemic developed a more active phase and a general feeling arose among the public that the authorities were concealing the real position of matters. The advantage of continuing the daily announcement just now is obvious. It offers the most practical and substantial proof that the disease is rapidly declining and that the measures adopted by the health department are proving efficient. The Lord Provost has appealed to the press to avoid the presentation in anything like a sensational form of the facts of the epidemic. Unfortunate and painful as some of these have been it is only fair to remember that the disease has been present in the city for many months and that the total number of cases and the deaths due to the disease have been spread over a relatively prolonged period. It is no exaggeration to say that in many other places the outbreak has caused more excitement than it has actually produced in the city where it has occurred. This is largely due to the fact that the totals have often been presented without any intimation of the length of time over which the numbers have been spread.

The Inspection of Meat in Glasgow.

The report of the Health Committee dealing with this subject was discussed at a meeting of the corporation on April 15th and led to a somewhat acute difference of opinion. The report proposed that in addition to the detective system at present in operation by-laws should be made for the inspection of carcasses, &c., sent into the city, by veterinary and lay inspectors, for the marking of meat passed by the inspectors, and for the arrangement and regulation of premises in which the official inspections could be conducted. It was argued that under the existing system it was easily possible to smuggle food into the city, and that the present staff could not ensure adequate and efficient inspection. Against the new proposals it was urged that they would promote the sending of portions of carcasses without any history attached, would encourage the view that suitability for food purposes could be determined by inspection of the dressed carcass rather than by a knowledge of the processes of disease, and would vitiate the principle that a wholly satisfactory examination of meat can only be made at the time of slaughter. Rather than to endeavour to add to existing local powers as was proposed, the right proceeding, it was claimed, was to move in the direction of securing an imperial law rendering it necessary for every carcass to be examined and certified at the time of killing. After an interesting debate the new proposals were adopted by a considerable majority.

Glasgow Hospitals.

It is announced that the King has been pleased, by warrant under His Majesty's royal sign manual, to direct letters patent to be passed granting a supplementary charter to the Glasgow Royal Infirmary. Mr. Thomas Jenkins has presented to the Samaritan Hospital for Women about 120 volumes of standard works on gynæcology and several cases of surgical instruments which were the property of his late son, Dr. Thomas Jenkins. Dr. Jenkins was gynæcologist to the dispensary of the Victoria Infirmary and his recent sad death at the outset of a career full of promise caused deep and widespread regret.

Medical Practitioners and Unqualified (Pharmaceutical) Assistants.

The report of the committee appointed some weeks ago at a meeting of practitioners held in connexion with a recent prosecution of a medical man before the General Medical Council was presented to a second meeting held in Glasgow on April 17th. It recommends the presentation to the Council of a memorial praying the Council to reconsider the matter and in any case not to lay down any general doctrine to the effect that the employment by a registered medical practitioner of an unqualified person to sell drugs and poisons is "infamous conduct in a professional respect." The memorial was adopted by the meeting and a deputation of eight practitioners was appointed to present it to the General Medical Council.[1]

April 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

AT a meeting of the President, Vice-President, and Council of the Royal College of Surgeons in Ireland held on April 18th Mr. F. Conway Dwyer, M.D. Dub., F.R.C.S. Irel., was elected Professor of Surgery.

Death of Dr. William Moore.

I regret to announce the death on April 18th of Dr. William Moore, ex-President of the Royal College of Physicians of

---

[1] Further particulars with regard to the memorial will be found on p. 1228 of our present issue.—ED. L.

Ireland, and late Crown Representative of Ireland upon the General Medical Council.

The Opening of the New Richmond Surgical Hospital.

The medical event of the week in Dublin was the formal opening by his Excellency the Lord Lieutenant of the new Richmond Surgical Hospital on April 20th His Excellency, in declaring the handsome building in North Brunswick-street open, congratulated the governors on possessing a magnificent hospital, which had before it a prospect of a long and useful career. Addresses were also delivered by the chairman (the Right Hon. T. A. Dickson, P.C.), Lord Iveagh (whose hospital corps in South Africa was manned by the staff of the Richmond Hospital), Viscount Powerscourt, Sir William Thomson, Sir William Findlater, Sir Thornley Stoker, and Mr. Thomas Myles (President of the Royal College of Surgeons in Ireland).

The Sanitary Condition of Howth.

At a meeting of the North Dublin Rural District Council held on April 17th the clerk submitted a report made by the medical inspector of the Local Government Board on the sanitary condition of Howth. The inspector stated that the outbreaks of diphtheria drew special attention to the need that existed at Howth for a properly devised system of sewerage and drainage. As regards the public drinking water-supply the report stated that the supply of drinking-water was derived from public pump wells (about 10), the majority of which were surface wells There were one or two open surface wells, which were very liable to pollution. In the very centre of the town, in the main street, there was an open or dipping well immediately adjoining dwelling-houses, which was extremely liable to pollution. This well should be closed, or measures taken to protect it and to convert it into a covered pump well.

Queen's College, Belfast.

On April 17th an important public meeting for the purpose of inaugurating a scheme for the better equipment of Queen's College, Belfast, was held in the Students' Union of the College. Interesting speeches were delivered and it was announced that Sir James Musgrave, Bart., D.L., would contribute £5000 to be devoted to the foundation of a chair of pathology. The Right Hon. W. J. Pirrie, D.L., has promised to provide a new laboratory of natural philosophy and engineering. The Lord Mayor (Sir Daniel Dixon, D.L.) has decided to provide an athletic field for the students. Mr. John M'Connell, J.P., has given £1000 to be used in the direction of establishing a faculty of commerce, or, failing this, for the establishment of evening classes. Some of the members of the medical faculty have promised a sum of £1000. The High Sheriff of Belfast (Mr. Otto Jaaffe, J.P.) has contributed £500, his Honour Judge Barkley £200, and two other friends £25 each. At the present time Belfast is entirely a Government college, but this interesting movement has emphasised the fact that it would greatly strengthen it and ensure public confidence if it had a board of governors or senate with local representative men on it. Being a Government college, as one of the local Belfast newspapers points out, its "government is narrow, antiquated, and totally at variance with modern views and practice." It has also been urged that the connexion of the college with Dublin Castle should be severed and that a new charter should be issued constituting it a self-governing institution on the representative principle. A committee with secretaries and treasurers has been appointed with the object of raising this new endowment fund for Queen's College. It is to be hoped that the scheme will be successful, though many true friends of the college regard the present time as inopportune, and think that it would have been wiser to have postponed the appeal until some indication was forthcoming as to the recommendations of the Royal Commission.

Irish University Education.

The proceedings of the last week have produced another example of the "topsy-turvy" condition of this most difficult of all Irish questions. In connexion with the projected new scheme for the better equipment of Queen's College, Belfast, there has been so much writing and discussion in Belfast as to the authorities of that college being in favour of sectarian universities that the President, to allay public feeling, had to make a very clear statement at the college meeting that neither he nor the college professors wished to turn it into a sectarian place of education in any form or degree. But matters did not end even with this statement, for at a meeting of the Belfast Conservative Association the Marquis of Londonderry (the President) declared that he "considered the establishment or the creation of a Roman Catholic university for Ireland absolutely unnecessary. He believed that it would be absolutely unworkable, and he considered that it would be unfair to the Protestant population of the country to ask them to contribute to maintain a university over which they had no control." These are rather remarkable statements coming from the Postmaster-General who is a member of the same Cabinet in which are Mr. Arthur Balfour and Lord Cadogan, who have both specially pleaded for the establishment of a Roman Catholic university. Lord Londonderry had to make this very strong declaration, it is said, because it was brought home to him that his party in Ulster looked with the gravest suspicion on the appointment of the coming Commission in reference to Irish university education. During his recent holiday in Ulster the Postmaster-General has been most carefully eliciting the views of educationalists and others on the university question, and hence his speech is all the more remarkable It shows clearly that even in the present Cabinet there are men who differ as widely on this vexed question as do people living in Ireland itself. Then, again, the debate in the House of Commons on April 22nd showed that even the Roman Catholics of Ireland are not quite agreed as to the Commission, for Mr. Dillon stated (and Mr J. Redmond agreed with him) that the Nationalist party had no responsibility for the issue of the Commission. "We did not ask for it, and we were not consulted about it, nor, as far as any intimation reached me, did the Irish hierarchy ask for it, and I feel confident that the hierarchy of Ireland would not make themselves responsible for the referring of this question to a Commission without consulting with the Irish Party." In the debate which followed a good deal was said as to whether Trinity College should be included in the matters to be considered by the Commission Originally the Lord Lieutenant said that Trinity College was to be excluded from the subjects referred to the Commission for consideration, but the Presbyterians of Ireland have demanded that Trinity College and the University of Dublin should be included, and it is evident from Mr. Dillon's speech that the Nationalist party are of the same opinion. Such a pass have things reached that the authorities of Trinity College have become most uneasy and Junior Fellows have urged in a memorial to the governing body of Trinity College the desirability of intimating to the heads of the Roman Catholic Church and of the Presbyterian Church in Ireland their readiness to provide facilities for the catechetical and religious instruction of their students by clergymen of their own churches and to invite their coöperation They also urge that negotiations should be entered into with the heads of the Presbyterian Church with the view to establish a Presbyterian Divinity School in Trinity The governing body made a very non-committal diplomatic reply. If the Royal Commission will only bring out clearly the facts apart from all sentiment or religious and sectarian bias, it may do something to lead to the settlement of this most vexed and perplexing of subjects

April 24th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

A Central Office for the Recovery of Medical Fees.

THE Association of Medical Men of the Seine, looking at the difficulties which so often arise with regard to medical men obtaining regular payment of their fees, have decided to start a central office, to which their clients will send their bills This office will undertake to collect the money and will charge a commission of 5 per cent. with a minimum of 50 centimes for expenses Disputed accounts will be looked after by a separate department, which will undertake all charges and expenses, charging merely a commission of from 20 to 30 per cent on the sum gathered in however little or much this may be The office will also keep a "black list" of persons who are known to be bad payers which medical men may consult, so that they will be put on their guard Everyone making use of this office will have to subscribe an annual sum of 10 francs, so that the working of the office may be upon a sound financial footing. It is not proposed to open the office until at least 300 persons are entered as subscribers. This is not the first establishment of the kind which has been tried, but the former ones were due to private enterprise and failed. It is to be hoped that the present attempt, which is undertaken with the official auspices of the medical association, will be a real success.

The Principles of Medical Deontology.

On April 5th it was announced that the Conseil Général des Sociétés d'Arrondissement had adopted the following principles of medical deontology. 1. Any medical man who is called in to attend a family for the first time shall, if he sees or becomes aware that he has merely been called in in the absence of the usual medical attendant, only give advice and treatment for so long as his professional brother is away. 2. Any medical man called in in the absence of another medical man who has been treating the case, may, if the patient expresses a wish to retain his services for the future, go on with the case provided that he informs the former medical attendant. 3. Any medical man who may be accidentally called in an emergency to a patient shall confine himself to prescribing such medicines and treatment as are immediately necessary and shall not return to the patient's house except in consultation with the usual medical attendant. 4. Any medical man summoned by a patient during the course of an illness, either acute or chronic, shall do his best to get the medical man hitherto in charge of the case retained. In case of failure the new attendant must at once acquaint the old one whom he succeeds. 5. Any practitioner called in as a consultant shall, while in presence of the patient or his friends, abstain from all comment on the treatment hitherto followed. The consultation should be held in private and the treatment recommended should be carried out by the ordinary medical attendant. 6. Any consultant, whether called in the first place by the medical man or by his patient, shall not pay a second visit without the cognisance of the general practitioner. 7. It is a mark of good fellowship to accept as a consultant the practitioner proposed by the patient or his family, whatever be his age or status, provided that his personal and professional honour are above suspicion. 8. A consulting-room is neutral ground, where a medical man may give advice to anyone coming to consult him without any regard to the medical man who usually looks after the patient in question.

Hygiene and Laundries.

At the meeting of the Academy of Medicine which was held on April 16th M. Delorme, surgeon-general (*médecin principale*) in the army and one of the professors at Val de Grâce, said that in his opinion laundry operations as at present practised did not afford sufficient protection to those people who feared the importation of microbes into their houses by reason of their own personal linen having been in contact with that of their neighbours who might very possibly be suffering from small-pox or other infectious disease. M. Delorme considered these fears as perfectly reasonable and wished that all directors of hospitals, asylums, and refuges should be made aware of them. Washing, as at present practised, includes soaking in cold water, soaking in lye, soaping, beating and brushing, rinsing and hand-wringing, or nowadays machine-wringing, drying, ironing, and folding. All these processes employ numerous hands and brutal machinery which destroys the linen, to say nothing of chemicals such as *eau de javelle*, sulphur, and the like, which are none the less destructive. M. Delorme forgot, however, that all these substances are for the most part strongly antiseptic and that a prolonged soaking in a boiling solution of soda deprives microbes of most of their powers for evil. The process which M. Delorme put forward and which the Assistance Publique has just adopted at the hospital in the Rue Michel-Bizot, and which is employed also at the Pasteur Hospital, is very simple. The linen is first soaked in a hot solution of bicarbonate of soda. It then passes into a large cylindrical stove which can be rotated in alternate directions. The axis of this stove is formed of a second hollow cylinder pierced with holes which allow the introduction of: (1) cold water, which washes out the soda solution; (2) steam under pressure, which converts the cylinder into a veritable disinfecting stove of a very perfect kind, for the oscillatory movements result in a thorough cleansing of a type not to be found in ordinary disinfecting stoves; (3) a hot solution of soap which, as the apparatus is kept in motion, effects a thorough cleansing; and (4) another current of cold water after half an hour or so, followed by more steam and lastly by a final rinsing current of cold water. The linen is then passed through a wringer and finally dried in a current of hot air. M. Delorme considers that this system provides for ideal washing and disinfection at the same time. Experiments made at the Pasteur Institute show that linen infected with all kinds of virulent microbes came out at the end of the operations perfectly aseptic. Only two persons are required to work the machine, which, besides being economical in working, takes up very little space. An ordinary cellar, provided that access for the clothes and a plentiful water-supply are provided for, will serve for the washing of the linen from a hospital of 500 beds. At the children's hospital in the Rue Michel-Bizot an ordinary mason with one assistant looks after the washing. The saving effected in one year at a charitable institution at Nanterre where 2500 kilogrammes of linen were washed every day was over 28,000 francs at the end of the first year. M. Delorme suggested that the Academy should recommend this apparatus for use in both civil and military hospitals as well as in private laundries.

April 23rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Battle of the Clubs in Leipsic.

STRIKES of medical officers of clubs have already taken place in several towns in Germany, such as Remscheid and Iserlohn, but none of them were so important as that which is now in progress in Leipsic. The club system existing in Germany has been several times described in THE LANCET,[1] and it will be recollected that membership of a club is compulsory on the working class, that the clubs are all under State control, and that the income of a considerable proportion of the medical profession depends on club practice. The committees of clubs have often taken advantage of their position to appoint medical officers on terms hardly compatible with their position as professional men, but in Leipsic, where matters recently came to a climax, the conditions of club practice have hitherto been relatively satisfactory. The Leipsic sick club had adopted the so called "free choice system," and had admitted nearly 200 medical men to practise in the club. The medical officers of the club always had a union of their own and a representative committee which was in communication with the executive of the club and assisted in settling disputes arising between medical men and club members. Of late the relations between the executive of the club and the medical committee became rather strained, the former alleging that the medical men did not sufficiently consider the financial interests of the club in their prescriptions, &c., and that the medical committee had not instructed the medical officers as to their duties in this respect. The executive of the club, moreover, declared that they would no longer recognise the medical committee, but would in future issue instructions to the individual medical men without its intervention. This they in fact did, and several medical officers were asked to call at the business premises of the club where they were discourteously reprimanded. The medical officers, therefore, gave notice that if matters were not put on a satisfactory footing within a week they would then cease to work for the club, and 156 of them—the overwhelming majority—accordingly took this course on April 5th. In thus breaking off their club practice they did not thereby leave the club patients without medical advice, but consented to attend them as private patients, charging fees to the individual cases. The club then proposed to invite medical men from other towns to settle in Leipsic, where they would be appointed medical officers to the club, the free choice system being thereby abandoned. The Leipsic medical chamber, however, informed aspirants to the vacancies that they would be required to appear before the court of honour if they agreed to the conditions offered by the club. The whole medical profession is on the side of their brethren at Leipsic. The Berlin Free Choice Society has issued a notice to its members informing them that they will not be re-admitted to the society if they go to Leipsic at the present time to aid the club in its conflict with the medical men The *Medical Reform* says that possibly some medical men with little money and less character might be tempted to come to terms with the club, but that such persons must be pitied rather than blamed for their ethical shortcomings The state of affairs at Leipsic has caused a sensation not only in the medical profession but in all circles of society The daily newspapers are publishing detailed telegrams descriptive of the strike and the measures taken on both sides, and their columns are filled with discussions on the disadvantages of medical practice in general and on the unattractive features of club practice Journals of every political bias, even those written for the working classes are unanimous in blaming the club and in congratulating the medical officers on the firmness of their attitude This is the first medical strike begun not for financial but for ethical reasons, and is on a greater scale than the previous strikes, which were nearly all unsuccessful owing to want of organisation Attempts at mediation have been tried at Leipsic, but have proved useless, and it is to be hoped that the club will be defeated

---

[1] THE LANCET, Oct. 22nd, 1898, p. 1093; June 17th, 1899, p. 1668; and Nov. 10th, 1900, p. 1390.

Organisation of the Pharmaceutical Profession

The *Official Gazette* recently published a Royal order relative to the new organisation of the pharmaceutical profession in Prussia, which will be conducted on lines analogous to those followed several years ago in the organisation of the medical profession A pharmaceutical chamber will be instituted for every province with power to discuss questions concerning the profession, and if the necessity arise it will be consulted by the provincial authorities The members of the chambers are to be elected by the qua[illegible] within the district, [illegible] representative Co[illegible] present, but if a member commits an ethical misdemeanour the chamber will be authorised to deprive him of the right of electing or being elected. Apart from the provincial chambers a joint committee will be instituted for the whole State, to which each provincial chamber will send one representative

Income of the Medical Profession in Berlin

The Medical Chamber of Berlin and the province of Brandenburg has issued an interesting report on the subject of the income of the medical profession residing in that district The chamber is authorised to fix an annual sum to be paid by every medical man for the expenses of the chamber and the support of distressed members of the profession It had been decided that a uniform rate of 10 marks (10*s*) should be paid and an additional sum by those earning more than 5000 marks (£250) The chamber has been informed by the income tax officials that of 1946 Berlin medical men under the jurisdiction of the chamber 529 earned from 900 to 3000 marks (from £45 to £150), 273 from 3000 to 5000 marks (from £150 to £250), and 785 more than 5000 marks, the largest income amounting to 295,000 marks (£14,750) It appeared that 107 medical men had no taxable income at all and the income of 252 could not as yet be ascertained In the other towns of the province the proportions were similar to those found in Berlin, so that 4 per cent of all the medical men had no taxable income, 26 per cent had an income from 900 to 3000 marks, 17 per cent from 3000 to 5000 marks, and 40 per cent more than 5000 marks In 13 per cent no reliable information could be obtained

April 22nd

ROME

(FROM OUR OWN CORRESPONDENT)

Professor Bizzozero's Successor

THE medical faculty of the University of Turin has unanimously resolved to invite Dr. Camillo Golgi, LL D Cantab, professor of general pathology in the University of Pavia, to fill the chair left vacant by the death of their colleague, Dr Bizzozero Dr Golgi's great work in histology, his classical studies in malaria, and his reputation as Dr Bizzozero's most distinguished pupil, were recommendations not easily found united in possible candidates for the chair.

A Case of "Siamese Twins"

Dr Francesco Caruso, *privat-docent* in gynæcology in the Neapolitan School, has just reported on a case of monstrosity resembling that of the Siamese Twins It comes under the category of "sternopagi"—that is, of two infants joined face to face from the upper part of the thorax to the umbilicus, this latter being common to the two They are both of the female sex, in fair health, and take the breast freely from the mother, a peasant woman of Marianella If, as is not unlikely, they should live, Dr. Caruso and other consultants deprecate surgical intervention, as contra-indicated by the disposition of the thoracic organs

A Great Medical Philanthropist.

"Having made Italy, we have now to make Italians," said Cavour's successor, Massimo D'Azeglio, and to carry out this consummation, so "devoutly to be wished," Dr Pietro Panzeri devoted all his faculties, original and acquired He "began at the beginning," and after graduation at the University of Pavia, made the rescue and rehabilitation of mal formed and mal organised children his professional *métier* For well nigh 30 years he laboured among the poor of Milan, bringing under special treatment every infantile victim to faulty or feeble development, and earned a truly wonderful reward in rearing thousands of apparently hopeless cases to the normal stature and strength, physical and mental, of their more fortunate fellows Milan was the headquarters of his practical work and there he brought the "Istituto dei Rachitici" founded by a kindred spirit, Pini, to its present high state of efficiency At Bologna he was *privat docent* in "Orthomorpheia," as it is called in Italy, and initiated successive relays of workers in the *métier* he had made his own Whatever energy he could spare from his special task he dedicated to promoting the interests of the profession and the cause of public hygiene, acting as communal assessor and councillor mainly with this object A native of Sormanno, in the province of Como, he was but 52 years of age when he died, leaving behind him a noble record of philanthropic work inspired by true patriotism and directed by rare professional skill.

April 21st.

CANADA.

(FROM OUR OWN CORRESPONDENT)

McGill University

MCGILL UNIVERSITY has in the past received most liberal support from the generous citizens of Montreal, and the end apparently is not yet Sir William Macdonald, who has already contributed $2 500,000 to the funds of the institution, has again announced that he will further subscribe to the extent of $150,000 Of this amount $75 000 will go to endow the chair of Chemistry, $62 500 for the chair of Botany, and $12,500 will be added to the chair of Physics By reason of these gifts there will be released the sum of $150,000 which has in the past been used for these endowments, and this will be taken and applied to the improvement of the arts course Miss Jessie Dow has also contributed $60 000 for the chair of Political Economy Lady Strathcona and the Hon Mrs Howard will bear the expense of a new wing to the medical building which will be erected during the course of the coming summer It will be four storeys in height and will be supplied with lecture theatres, museums, and chemical laboratories

Cremation in Quebec.

Some little time ago Sir William Macdonald of Montreal offered to defray the cost of the erection of a crematorium in the Mount Royal Cemetery of that city For this purpose it was found necessary to have legislative authority. A measure for this purpose was therefore introduced into the Quebec Legislature during the session which has just closed, and after considerable opposition it finally passed that House by a majority of one and the Legislative Council of the province by a vote of eleven to seven, the opposition coming chiefly from the Roman Catholics The Bill provides "that the deceased at the time of his death is entitled to be buried in Mount Royal Cemetery, and has expressed by his will a wish that his body be cremated"

Toronto University

A measure of relief has been introduced by the Government into the Legislature of Ontario for Toronto University, the senate of which by a very large majority now favours a change of name to the "University of Ontario," pointing out that it is the only State-aided university in North America which takes its name from the city in which it is located. For the past three or four years Toronto University has been financially embarrassed, and has practically gone behind in that time to the extent of $30,000 or $40,000. The governmental relief will give the university $20,000 this year; and in the supplementary estimates there is provision for $50,000 more to commence the immediate erection of a new science building, the total cost of which will be about $200,000. The Bill further provides that the government of the university shall be invested in a board of trustees. This change is made to tempt wealthy Torontonians who in the past have taken no financial interest in the affairs of the university. McGill University, which is not under State control, prospers wonderfully by the acts of wealthy Montrealers; and by placing Toronto University under the management of a board of trustees it is thought that the moneyed men of Toronto will not hesitate in coming to its assistance.

Hospital Work off Labrador.

Dr. W. T. Grenfell, who for the last 11 years has been superintending missionary work among the fisher-folk in Labrador, recently addressed a meeting in Montreal where he gave some interesting details of hospital work in that country. In Labrador there are three hospitals, one at Battle Harbour, another at Indian Harbour, and a third now under course of construction at St. Anthony on the North French Shore. In addition to these there is the hospital ship *Strathcona*, of which the medical officer is captain, which is equipped with six beds and all necessary appliances, including x-ray apparatus. This ship constantly cruises up and down the coast and last year handled 1020 cases. Dr. Grenfell expressed his gratitude to Dr. T. G. Roddick, M.P., who had given great assistance in the work.

A Consumption Sanatorium for Nova Scotia.

Nova Scotia will soon have a consumption sanatorium. About a year ago a committee was appointed by the Government of the province to report on the question of a site, the style of building, management, &c., and this committee have had their report laid before the Legislature by the Premier of the province, the Hon. Mr. Murray. The committee recommend that the location be either at Dutch Village, on the Atlantic seaboard, near Halifax, or on the shore of Bedford Basin, near the village of Bedford; that accommodation be provided for 20 patients; that no resident medical officer be appointed, but a trained female nurse as lady superintendent; and that regular specified visits be made by two qualified medical men every week. Dr. Reid, the secretary of the Nova Scotia Board of Health, disapproves of the site near Halifax. He is further of the opinion that better results are obtained where a medical man is in residence as superintendent.

Winnipeg General Hospital.

The board of governors of the Winnipeg General Hospital held their annual meeting on Feb. 28th. The annual report showed that the number of patients treated in this institution during the past year numbered 2649, and that in the out-door departments there were 1435 consultations. The financial report showed a deficit of $4510.50, which was due to the fact that the hospital had had to cope with a small-pox outbreak within its walls during the early part of the year.

Proposed Dominion Medical Council.

Dr. T. G. Roddick, M.P., has introduced his Bill for a Medical Council for the whole Dominion of Canada. It provides that each province (of which there are seven) and the North-West Territories shall have each three members on this board—in all 24 from the regular profession of medicine. As there are some homœopaths in the province of Ontario who have representation on the Ontario Medical Council these will also be allowed three members on the Dominion Board to be elected by themselves. The 24 members of the regular school will be appointed as follows: the president of each provincial medical council *ex-officio*, one member to be elected from the medical councils of each province, and one to be appointed by the Governor-General in Council from each province, and for all such purposes the North-West Territories are considered as a province. In his address before the House Dr. Roddick gave the medical population as follows for the Dominion of Canada: Ontario, 2500 practitioners; Quebec, 1400; Nova Scotia, 476; New Brunswick, 243; Prince Edward Island, 90; Manitoba, 344; British Columbia, 214; and North-West Territories, 95. If this Bill becomes law it will be necessary for each of the provincial legislatures to enact a short amendment to their medical acts.

Canadian Medical Men in the Imperial Services.

A very gratifying announcement has just been made by the Canadian Militia Department to the effect that there is at present a Bill before the Imperial Parliament which will provide for the admission of the medical men of the colonies to the Imperial naval, military, and civil services. It is understood that the measure in question will provide that where the examinations and courses of study at the principal colonial schools of medicine are the same or equivalent to those of the schools of the United Kingdom the candidates shall be admissible to either of these services. At the time the Canadian contingents were being despatched to South Africa surgeons of the highest standing in Canada and holding commissions from Her late Majesty in the militia volunteered for service there, and even a complete field hospital was offered by Canada, but in both cases the War Office was forced to refuse such service because it was contrary to the British Medical Act of 1858. Through the passage of this Bill this disqualification will be removed, and there is no doubt that Canadians as well as other colonial surgeons will hail the adoption of such legislation with complete satisfaction.

Vital Statistics from Quebec.

The sixth annual report of the Board of Health of the Province of Quebec contains some interesting details. In some respects that province is in advance of the other provinces of the Dominion, particularly as regards its birth-rate and the prevention of tuberculosis. Every householder now, in the province of Quebec, in whose household there occurs a death from consumption must notify the secretary of the local board of health within 48 hours of the date of such death, and then upon such notification having been given the municipality is bound to cause the disinfection of the apartments which have been contaminated by the patient. This law came into effect on June 7th, 1900. The recorder of statistics for that province has given some figures concerning the death-rate from tuberculosis in some of the Canadian cities, and it would appear that Quebec city is the least affected and Ottawa, the capital, the most. The death-rate in Quebec city from tuberculosis is 1·99 per 1000 of the population; that of Ottawa is 3·12, of Montreal 2·87, of Kingston 2·17, of Toronto 2·41, and of London 2·67. These figures compare favourably with Paris at 4·90 and New York city at 3·60. The birth-rate of Quebec province was 35·7 per 1000 in 1898 and 33·4 per 1000 in 1899.

The Metric System.

Lieutenant-Colonel Burland, Montreal, is interesting himself in the formation of a metric association the object of which is to prepare the people of Canada for the adoption of the metric system. The Hon. Mr. Bernier has accepted the honorary presidency. The association will seek to continue in a more extended way the work which has already been begun by the Canadian Government.

Toronto, April 4th.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

Yellow Fever and Mosquitoes.

AT the recent Pan-American Medical Congress held in Havana, Cuba, a committee reported a final statement of the results of their investigation made at the experimental sanitary station (Camp Lazear) near the town of Quemados, Cuba. At this station, under strict quarantine and with all other sources of infection absolutely excluded, they succeeded in infecting 85·7 per cent. of those individuals who had been bitten by purposely contaminated mosquitoes (culex fascinatus). Their observations did not confirm the opinion that mosquitoes carried the specific agents in their probosces and simply transferred it from one individual to another in a mechanical way, but appeared to demonstrate that the parasite of this disease must undergo a distinct cycle of development in the body of the mosquito before the latter was capable of conveying the infection. This period would seem to be not less than 12 days. They also considered the question of house infection and were able to show that this infection was due to the presence of mosquitoes that had previously bitten cases of yellow fever, and that the danger of contracting this disease might be avoided in the cases of non-immune individuals who slept in this building by the use of a wire screen. They also demonstrated by observations made at this camp that clothing and bedding contaminated by contact with cases of yellow fever and by the excreta of these patients were absolutely without effect in conveying this disease. They concluded that yellow fever was only propagated by the bite of the mosquito (culex) and that the disinfection of articles of clothing and bedding soiled by the excreta in this disease was no more required than in the case of like articles soiled by a patient with an attack of malarial fever.

The late Dr. Pepper of Philadelphia.

The late Dr. Pepper of Philadelphia was not only a scientific man of high attainments but a philanthropist of lofty ideals. Mr. Francis Norton Thorpe, writing in the *Century* magazine for February, 1901, says of him: "Dr. Pepper was the son of a physician, the celebrated 'Elder Pepper' as he is called to distinguish father from son. The father pursued advanced medical studies together with Oliver Wendell Holmes in Paris at a time when American students rarely went abroad. On his return to Philadelphia he became professor of the theory and practice of medicine in the University of Pennsylvania, acquired an extensive practice, and died in 1864 at the early age of 56 years. A few months before the father's death the son was graduated in medicine at the University of Pennsylvania. Great physicians are rare, and rarer is the man who is at the same time equally great as a man of affairs, as educator, and public benefactor. Such a man the son became. In 1870, at the age of 27, he projected the University Hospital and boldly set out to raise an endowment fund of $750,000. In less than four years he secured more than $500,000 (£100,000), including two appropriations of $100,000 (£20,000) each from the Legislature. The hospital was formally opened in 1874. Its creation was necessitated by the removal of the university from its old site, where the Post Office now stands. No such task had been done before by a citizen of Philadelphia, and its performance gave Dr. Pepper a position among the first men of the city. Dr. Pepper raised above $10,000,000 (£2,000,000) and secured about 100 acres of land from the municipality, lying near the heart of Philadelphia. To the execution of this task he gave the services of one of the most acute and at the same time most practical minds ever vouchsafed to man. To this service of his genius he added the personal gift of nearly 500,000 dollars (£100,000) which he earned in the practice of an exacting profession. It may be doubted whether any other American has run a like career. His sudden death of angina pectoris at Pleasanton, California, August 26th, 1898, occurred just as he had completed his fifty-sixth year." Dr. Pepper will be remembered by posterity as an eminent physician and as one of the most energetic philanthropists that the medical profession has produced.

Distribution of Mortality in New York City.

The health statistics of New York city reveal some curious and unexpected facts. The impression has always prevailed that overcrowded districts, insanitary surroundings, scantiness and poverty of diet, are the most important factors in determining the death-rate of a community, but from the statistics it would appear that the most healthy parts of New York City are those which are inhabited by the poorer classes, while in the quarters of the rich the death-rate is highest. An investigation has been made into the matter and the results have been published in a journal called the *National Provisioner*. The following are some of the examples quoted. The twelfth ward comprises within its boundaries one of the richest sections of the city with only 61·6 persons per acre, but among its population of 364,412 persons the total deaths were 2287, while in the thirteenth ward, which is inhabited entirely by the poorer classes, with 539 5 persons per acre, among its population of 56,602 persons the total deaths were only 196, the relative advantage being therefore greatly in favour of the thirteenth ward. Again, the Waldorf Astoria and Fifth-avenue society district is included in the twenty-first ward, which together with the nineteenth ward contains more multi-millionaires and millionaires than any other area of like extent in the world, but the mortality of these two wards, nevertheless, compares badly with that of the lowest quarters of New York. The twenty-first ward has 189 9 persons per acre, but among its population of 72,144 persons the total deaths were 442, whilst in the down-town slum district round the Bowery, Rivington-street, Norfolk-street, and Division-street, with 643 8 persons per acre and a population of 70,168 persons, the total deaths were 281. In the rich nineteenth ward, with 144·3 persons per acre, the total deaths in the population of 267,076 were 1575, whilst in the seventh ward, with 360 7 persons per acre, the total deaths in the population of 72,227 were only 403. The reasons for this seemingly anomalous state of affairs are not easy to give.

Condition of the United States Army in the Philippines.

The report of Colonel Charles R. Greenleaf, assistant surgeon-general United States army and chief surgeon in the Phillippines, has recently been issued and is full of useful information. The report covers a period of seven months, up to July 31st, 1900. With regard to the mortality of the army the report says: "The number of deaths in the army has steadily increased and a diminution of the death list can scarcely be expected. The number of men shot from ambush by small guerilla bands now exceeds those killed at any previous time and as time progresses and the men become more and more debilitated by tropical service the more marked will be the ratio of deaths. Gunshot injuries are the cause of the greatest mortality, with dysentery in the second place. There have also been a considerable number of deaths from typhoid fever, showing that the disease has gained a foothold in the islands. Dr. Greenleaf rightly lays much stress upon the supreme importance of sanitation both with armies in garrison and on the march, and expresses his satisfaction that American army medical officers are beginning thoroughly to recognise this fact. Owing to the scarcity of medical officers it has come about that, roughly speaking, 10,000 troops are serving at posts with practically no medical attendance. The number of posts in the Philippines was at the time the report was written 375 and was said to be constantly increasing. To fill these posts there were only 336 medical officers on duty in the islands.

April 13th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague.

THE bubonic plague, which was thought to have disappeared, has broken out again. Four cases have occurred near Brisbane, two at Perth, one at Adelaide, while one case was introduced into Sydney on a troopship from Cape Town and proved fatal. The inspection of vessels and the other precautions against the introduction of the disease have been commenced again at all the ports. The destruction of rats has been going on steadily all the time, and all precautions will be rigidly enforced, the health authorities earnestly appealing to householders to coöperate in securing a maximum of cleanliness and in making it difficult for rats to live.

The Health of Sydney.

Mr. T. M. Kendall, medical officer to the Sydney Water and Sewerage Board, has presented his annual report on the health of the metropolis for the year 1900. He stated that, compared with the preceding year, the death-rate had increased, especially from diphtheria, diarrhœa, and typhoid fever. Deaths from phthisis had decreased. The mortality from typhoid fever was greater than it had been since 1896 and the disease was not confined to areas where it had been noted in former times, but had occurred in supposed healthy zones. The increase was probably attributable to neglect of householders in not keeping the house drainage in order. The greatest number of deaths from typhoid fever was reported during December. The highest temperature registered was also in December—viz., 104·1° F. on Dec. 12th. The rainfall was greater than it had been for several years, exceeding that of 1899 by 10·37 inches. The population had increased in the metropolis by 11,350. In the report of the health officer of the city of Sydney to the City Council it was stated that typhoid fever was likely to be as bad this summer as it was last summer. It is suggested that further legislation is necessary to provide means of making various diseases notifiable, when so proclaimed, without being infectious diseases under the Health Act, such as beri-beri, arsenical and phosphorus poisoning, lead poisoning, anthrax, &c.

Lunacy Administration in Victoria.

Reference has previously been made to the urgent necessity for reform in connexion with the lunatic asylums in Victoria. Dr. McCreesy, the Inspector-General of Asylums, has over and over again called attention to the need for important changes in the department. In his last report he stated: "For some years it has been felt by the medical staff that the lunatic asylums are not giving the patients all the advantages that are obtainable from modern medical treatment." One crying need is the provision of paying wards for the class of cases usually sent to private institutions in other countries. Thirteen years ago the present Lunacy Act was passed, and one of its provisions is that no private lunatic asylums are permitted. The State, however, has failed to make adequate provision for the well-to-do insane and consequently the Act is practically evaded. Places known euphemistically as homes or retreats are established by private enterprise and are under no sort of control. The patients in them are really insane, but as they are not so certified it is impossible to prove that the Act has been evaded. The publicity given to an unfortunate case in which an inmate of one of these institutions committed suicide has once more directed attention to the state of the law as to lunacy and the treatment of the insane in Victoria The press has been demanding reform for years, but Government after Government has allowed matters to drift. Investigation and reform are promised now and it is to be hoped that something will be done. Mr. W. Beattie Smith, medical superintendent of the Kew Asylum, has been granted leave of absence to visit Europe and America and will no doubt bring back with him the latest information on lunacy administration in the older countries.

Medical Men and Alcohol.

At a recent meeting of the council of the New South Wales Alliance (a temperance association) the following declaration was read. It had been signed by Dr. P. Sydney Jones, Dr. R. I. Ward, Dr. C. A. Dagnall Clark, Dr. B. J. Newmarch, Dr. W. Sheldon, Dr. F. H. Kyngdon, and Mr. C. Rorke.

> We, the undersigned, recognising the widespread ignorance prevailing with regard to the nature and effects of alcoholic liquors and believing that much disease, insanity, pauperism, and crime in the community result from the indiscriminate consumption of these as beverages, feel called upon to make known the following facts 1. That perfect health is compatible with total abstinence from all alcoholic beverages. 2. That alcoholic liquors, instead of increasing, as is popularly assumed, rather decrease capacity for work, and should be expressly abstained from when extremes of heat or cold have to be borne 3 That the habitual use of alcoholic liquors in quantities conventionally deemed moderate is often productive of serious disease. 4 That alcoholic drinks should never be given to persons suffering from ill-health or disease except by the advice of a medical man. 5. That no medical man should prescribe alcohol without a grave sense of responsibility, and that the quantity and duration of time for taking it should be definitely fixed.

This declaration has come in for a good deal of adverse criticism by the lay press as giving very little information.

Presentation to Dr. T. H. Fiaschi.

Dr. T. H. Fiaschi, of the Army Medical Corps, was entertained at a complimentary smoking concert by the representatives of the wine industry, to welcome him back from the war in South Africa where he has rendered such signal service. Dr. Fiaschi was presented with a very handsome illuminated address, which read as follows:—

> To Major Thomas Henry Fiaschi, Army Medical Corps, New South Wales, M D, Ch.D. Pisa and Florence, Italy—Dear Sir,—As representatives of the wine industry of New South Wales we are desirous of presenting you with this address of welcome as a mark of our appreciation and recognition of your unremitting and valuable services in connexion with viticultural pursuits. Whilst we are pleased at knowing we have amongst us one who has devoted so much time and trouble to the furtherance of the industry with which we are so closely identified as your esteemed self, we cannot allow the occasion to pass without in some way recognising your many and humanitarian services rendered at the front during the South African campaign.

Cases of Apparent Death.

Some sensation was caused recently at the Newcastle Hospital. An old man was brought there and when examined by the medical officer was pronounced to be dead. The body was then removed to the morgue. A little time afterwards movement and heavy breathing were observed and it was found that the man was alive. He was removed to a ward, but he died a few minutes later. When he had been first examined no pulse could be felt and there was no respiration. A somewhat similar case occurred a short time previously at Fitzroy, Melbourne. A patient was pronounced to be dead by a local medical man but later was found by the friends to be alive and was removed to St. Vincent's Hospital, where he lived for some days, dying ultimately from uræmia.

What is Medical Advertising?

On Jan. 2nd the Sydney *Daily Telegraph* published a special Commonwealth issue, a portion of which was devoted to short articles under the heading "Glimpses of the Century." The medical subjects and writers were respectively:—Surgery: A. MacCormick, M D. Edin. Malaria: W. Camac Wilkinson. Medicine: A. Jarvie Hood, M.B., C.M. Glasg. Dealing with the Insane: Chisholm Ross, M.D. Sydney. Sanitation: T. Mailler Kendall, L.R.C.P. and L R C.S. Edin. Use of Serums in Disease: W. Camac Wilkinson, M.D. Treatment of Inebriates: J. M. Creed, M.D., M.L C. The names of these professional men were printed over the respective articles and their facsimile signatures appeared beneath them. The subject was brought under the notice of the council of the New South Wales Branch of the British Medical Association, which passed the following resolutions:—

> That the attention of the council of the New South Wales Branch of the British Medical Association having been called to a series of articles in the Sydney *Daily Telegraph* of Jan. 2nd, 1901, over facsimile signatures of the authors, the council regrets to find that some of the contributors are members of this branch. The council considers it undesirable that signed articles on medical subjects should appear in the lay press
>
> That the foregoing resolution be forwarded to the authors of the signed articles who are members of the branch, with the expression of a hope that each contributor will offer some explanation as to the appearance of his signature.

It is understood that the contributors intend quietly to ignore these resolutions.

Standard Strength of Liquors.

The Board of Health of New South Wales has recommended the following standard strengths for spirituous liquors: whisky and brandy, 25·0 under proof; rum, 30 0 under proof; and gin, 35·0 under proof.

Obituary.

Mr. John E. W. Cruise, M.B., B.Ch., B.A.O. R.U.I., died recently at Orange, New South Wales, at the age of 36 years. He was a son of Sir Francis Cruise of Dublin. He had been practising at Orange for seven years and was held in high esteem by a large circle of personal friends as well as by his numerous patients, for he was a very capable practitioner. The cause of death was cerebral hæmorrhage.—A well-known figure has been removed from the medical circles of Sydney by the death of Mr. Robert Hunter, L R.C.P. & S. Edin., of Jamieson-street. He was a native of Kilrea, Derry, Ireland. He landed in Sydney in 1873, and was at first assistant to the late Dr. Charles M'Kay, but four years later he started an independent practice. He was noted for his charitable and philanthropic disposition.—One of the oldest county practitioners in Victoria died recently in the person of Dr. Samuel Reynolds who had been practising in Mansfield for over 40 years and was 77 years of age at the time of his death.

March 12th.

Obituary.

WILLIAM MOORE, M.D. DUB., F.R.C.P. IREL.

DR. WILLIAM MOORE, of 67, Fitzwilliam-square North, Dublin, who died on April 17th in his seventy-fifth year, had been for a great many years one of the foremost representatives of his profession in Ireland. The son of a medical man, he chose a similar path in life for himself and received his medical education at Trinity College, Dublin. In 1850 he was admitted a Licentiate of the Royal College of Surgeons in Ireland and graduated as M.B. in Dublin University. In 1855 he became a Licentiate of the King and Queen's College of Physicians (now the Royal College of Physicians of Ireland), in 1859 the Fellowship was conferred on him, and in 1883 he had the honour to be elected President. In 1860 he took the M.D. degree at his University. From 1868 to 1883 Dr. Moore was King's Professor of Practice of Medicine in the School of Physic in Trinity College. He was also an examiner in clinical medicine at Trinity College, physician to Sir Patrick Dun's Hospital, and physician to the National Hospital for Children. In 1885 he succeeded the late Dr. Benjamin George MacDowel as physician-in-ordinary to the Queen in Ireland and after Her Majesty's death last January he received the appointment of physician-in-ordinary to the King in Ireland.

Dr. Robert Lyons, nominated by the Crown to represent Ireland in the General Medical Council, died in 1886, and the vacancy thus created was filled by Dr. Moore, who was a member of the Council from January, 1887, to November, 1897, when he resigned Dr Moore was a member of many learned societies, and had been President of the Pathological Society and of the Section of Medicine of the Royal Academy of Medicine in Ireland. He was a man of mark, not only in Dublin but also in the North of Ireland. He had a country residence called Moore Lodge at Ballymoney, Antrim, of which county he was high sheriff, and his eldest son, Mr. William Moore, K C, was elected Member of Parliament for North Antrim in 1899 Dr Moore was the author of several small works on medical subjects, and he contributed many articles to the medical journals Among his separately published works may be mentioned "Infantile Mortality," 1859; "On Typhus and Typhoid Fever," 1871; and "On Epidemic Scarlatina," 1875 His contributions to periodical or serial literature included articles on Strumous Peritonitis, Idiopathic Tetanus, Aneurysm and Dementia, Cerebro spinal Complications in Continued Fever, Acute Rheumatism and Rheumatic Pericarditis, Affections of the Chest in Children, and Diseases of the Heart and Great Vessels

During his long life Dr. Moore had witnessed many improvements in medical practice and, it must be admitted, many changes in medical opinion. His mature judgment and well-trained mind predisposed him to caution in the accept- [illegible] mental attitude which was not [illegible] umstances, entrusted as he was [illegible] usual importance

GEORGE STONE, L R C P. & L R C S EDIN, L S A

THIS well known aural surgeon met his death on April 21st from an attack of pneumonia after a week's illness that indicated a very virulent type of infection. He was himself a man of apparently good constitution, who commonly enjoyed good health, and whose habits were both regular and frugal; in fact, everybody would have foretold for him a good prospect of long life As it is he died at the age of about 52 years, mourned by a very large circle of relatives and friends. Mr Stone began his medical studies in Liverpool and afterwards went to Vienna where he enjoyed the friendship and instruction of Professor Politzer whose methods [illegible] ne ear he largely followed [illegible] nslated from the German [illegible] stive work on the "Dis- [illegible] n aural and ophthalmic [illegible] the staff of the Liverpool Eye and Ear Infirmary About 15 years ago he gave up eye practice and confined himself to the study and treatment of ear disease, in which he enjoyed a reputation and a practice of the first rank He was a man of quiet but very courteous demeanour, with a somewhat retiring disposition, but possessed of the soul of honour, unflagging industry in the pursuit of knowledge and the welfare of his patients He had a great faculty for languages and was familiar with Spanish, Italian, French, Greek, and German, both colloquially and in a literary sense He was also a stenographer of many years' standing and well known by correspondence to other medical stenographers Mr. Stone will be missed not only by his immediate circle and neighbourhood, but from the international and other meetings of otologists where he was both familiar and respected

CHARLES KEARNS DEANE TANNER, M D R U I, L R C S IREL, M P

DR TANNER, whose death on the night of April 21st is announced, was the well known Nationalist Member of Parliament for Mid Cork Born in 1850, the son of the late Mr W K Tanner, M D, he received his education at inchester, Paris, Queen's College, Cork and the Universities of Leipsic and Berlin Had he continued in the practice of his profession he would very probably have made a brilliant success He graduated as M D and M Ch at the Queen's University and was for some time physician to several Cork hospitals, besides being demonstrator in Anatomy at Queen's College. But having elected to enter politics he sat continuously first as a Nationalist and after the split as an Anti Parnellite Nationalist for the Mid Division of county Cork In the House of Commons he certainly gained notoriety, but the game of politics has to be played in the House of Commons in a particular way, and Dr Tanner did not play the game as it should be played, and consequently never had the least influence over the assembly which he often outraged and sometimes amused Despite his frequent breaches of good manners and his irascible disposition he was a most kindly companion and popular among those who knew him well He was a "whip" of his party. Dr Tanner married a daughter of the late Captain John McDonnell Webb, formerly Captain Royal Irish Dragoons.

THOMAS WILSON, M D ST AND, M R C S ENG, L S A.

THE death is announced at the age of 82 years of Dr. Thomas Wilson He was the eldest son of the late Mr. Thomas Wilson, the Hull ship owner. Dr Wilson became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries in 1840, while in 1864 he graduated as M D at the University of St Andrews He practised for some time in Hull, but late in life retired to Scarborough where he died

THE REV RICHARD PRIOR WINTLE, M R C S ENG, L S A.

THE Rev Richard Prior Wintle died at Cowley St. John, Oxford, on April 16th, in his sixty first year Mr. Wintle assisted in the services at the church of St. Mary and St John, Cowley, on Easter Day, and, shortly after contracting a chill, pneumonia developed, to which he succumbed The deceased was the son of Dr F. T. Wintle of The Warneford, Headington, Oxfordshire He received his medical education at St George's Hospital and became qualified as M R C S Eng in 1863 He also held the diploma of L S A. He practised the medical profession for a few years, but in 1878 he entered the Truro Theological College and in 1880 was admitted to holy orders, his first curacy being at St Mary's, Truro, with Canon Harvey. He was subsequently rector of Weston in Gordano, near Bristol, and later curate of Frome Selwood, Somerset Until recently he was for several years a member of the clerical staff at Holy Nativity Church, Knowle, a suburb of Bristol, where he gave his services voluntarily and only left on account of ill-health Mr Wintle was a member of the council of the Guild of St. Luke and took great interest in the work of the society. His quiet and kindly manner endeared him to a large circle of friends in Bristol and the district and sincere sympathy is felt with Mrs Wintle, more particularly in the parish of Knowle, where Mr Wintle was regarded with much affectionate esteem

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In April the following candidates passed in the subjects indicated:—

Surgery.—P J R. Bucknill (Se [illegible]
T Burdekin, University Coll [illegible]
Hospital, A W H Grant ([illegible]
Hospital W J *Hogg* (Secti [illegible]
pital F A Hort Middlesex [illegible]
and II), St. Mary's Hospi [illegible]

Medicine.—K M *Betts* (Section I), Royal Free Hospital P J R. [illegible] and Dublin, W H Crossley,
B [illegible] (Sections I and II),
S [illegible] Middlesex Hospital,
C [illegible] Garstang (Section I),
L [illegible] and II), St. Thomas's
M [illegible] ham R. F Lamport,
Hospital H Jessop (Section I) [illegible]
Royal Free Hospital and A. H Thomas (Sections I and II).

[illegible] ptist, Calcutta,
[illegible] ke, St Thomas's
[illegible] iversity College
[illegible] Hospital G B
[illegible] g, Manchester.
[illegible] T Harris,
[illegible] Hospital A F
[illegible] St. Mary's Hos-
pital; D V Muller Charing Cross Hospital, H Richardson, Leeds F R Rislen, St. Bartholomew's Hospital, and A H. Thomas, St Mary's Hospital

Midwifery.—L A F Baptist, Calcutta, F M Boclet, Charing Cross Hospital, C W S Boggs Leeds V Garstang Manchester, M S W Gunning, University College Hospital; L. R. Marshall, St Mary's Hospital; S. A. Mahmood and W. Miles, Middlesex Hospital; A. U. Parkhurst, Cardiff and St. Mary's Hospital; B. E. Sansom, St. Thomas's Hospital; T. Scatchard, Leeds; and A. W. D. Thomson, St. George's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: T. Burdekin, A. W. H. Grant, F. A. Hort, H. Jessop, E. F. Lamport, L. R. Marshall, and R. A. Pitter.

University of Birmingham.—At the examination for the Diploma in Public Health held in April the following candidates were successful:—

Parts I. and II.—Francis William Bonis and Aaron Sims.

University of Durham. — At the second examination for the degree of Bachelor in Medicine, held in April, the following candidates satisfied the examiners:—

Old and New Regulations.

Anatomy, Physiology, and Materia Medica.—First Class Honours: James William Gibson, College of Medicine, Newcastle-upon-Tyne. *Second-Class Honours:* Fred Stoker, Walter Haward, and William John Phillips, B.Sc., College of Medicine, Newcastle-upon-Tyne; and John Spencer Hall, M.R.C.S., L.R.C.P., St. Thomas's Hospital. *Pass List:* Frederick Durnford Atkins, St. Thomas's Hospital; Frederick George Armstrong, College of Medicine, Newcastle-upon-Tyne; Cyril Prichard Burd, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital, James Alexander Bennett, College of Medicine, Newcastle-upon-Tyne; John Frederick Bridge, Birmingham University; Harold Linton Currie, William Gibbons, Albert James Gilbertson, Alfred Herbert Heslop, Thomas Charles Hunter, Lizzie Evelyn Kendal, and Bernard Warner Lacey, College of Medicine, Newcastle-upon-Tyne; Sidney Nix, St. Mary's Hospital; Donald Murray Ross and Mary Raw, College of Medicine, Newcastle-upon-Tyne; Douglas Montague Brooking Snell, St. Thomas's Hospital; Thomas John Samuel Suffield, L.R.C.P., L.S.A., London Hospital; Janet Arthur Vaughan, London School of Medicine for Women; and Hermann Wolfe and William Frank Wilson, College of Medicine, Newcastle-upon-Tyne.

Cost of Vaccination.—At the meeting of the Falmouth Board of Guardians held on April 19th it was reported that the cost of vaccination by the guardians during the past 12 months had amounted to £527.

Two ladies have just passed the German State Examination for medical practitioners in Freiburg, Baden, both obtaining the mark "very good." These are, it is stated, the first ladies to qualify in the ordinary way in the German Empire.

Increase of Salary.—At a meeting of the Somerset County Council held on April 9th it was decided to increase the salary of the county analyst (Dr. H. J. Alford) from £150 to £200 per annum. Dr. Alford has held the appointment for nearly 20 years, during which time he has analysed 20,456 samples.

Notification of Measles and Chicken-pox.—At the meeting of the Dartmouth Town Council held on April 9th it was decided, upon the recommendation of the sanitary committee, that measles and chicken-pox should be removed from the schedule of diseases notifiable under the Infectious Diseases Notification Act. The medical officer of health was instructed to give the authorities of H.M.S. *Britannia* immediate notice of any case of infectious disease occurring in the town.

Charing Cross Hospital.—On St. George's Day, April 23rd, a special *matinée* was held at the Pavilion Music Hall in aid of Charing Cross Hospital. The entire staff and orchestra of the Pavilion gave their services for the occasion and, as was fitting, roses were much in evidence. Altogether there were 36 "*turns*," in which most of the prominent theatrical and music-hall artists were represented. Tea and coffee were gratuitously supplied by Mrs. Robertson of New Bond-street. Messrs. Bechstein lent the grand piano and a sum of £230 was taken at the doors. Warm thanks are due to all who so kindly gave their time and skill towards affording help to the sick and needy.

Royal United Hospital, Bath.—On April 12th a meeting was held at the Bath Guildhall, under the presidency of the Mayor, in support of the Royal United Hospital, Bath. The Rev. E. Handley, President of the hospital, stated that the overdraft at the bankers now amounted to £3500. The Earl of Cork, Lord Edmund Fitzmaurice, Sir John Goldney, Canon Quirk, and others made speeches in favour of the hospital and pleaded for more financial support. £155 were subscribed at the meeting and it was decided to recommend that collections should be made at the various places of worship on Nov. 3rd in aid of the hospital and that subscriptions should be raised in the various towns and villages around Bath for the same purpose.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Thursday, April 18th.

The Budget.

The proposals of the Budget introduced at this sitting by the Chancellor of the Exchequer were 2*d.* on the income-tax, making it 1*s.* 2*d.* in the £1, a duty on sugar of roughly speaking ½*d.* per lb., a duty on export coal of 1*s.* per ton, suspension of the Sinking Fund for another year, and borrowing powers to the extent of £60,000,000. In dealing with the sugar-duty the Chancellor of the Exchequer explained that glucose, used principally for the manufacture of jam, aerated waters, and beer, and containing about 45 per cent. of pure sugar, would be taxed at the rate of 1*s.* 8*d.* per hundredweight.

Meat for the Army.

Lord Stanley announced in reply to a question that the terms of the new contracts for the supply of meat to the army would exclude foreign meat.

Monday, April 22nd.

Death Certification.

Lord Hugh Cecil asked the Secretary of State for the Home Department (1) whether his attention had been called to the certificate of death given in the case of a certain Lily Graves; (2) whether he was aware that it was alleged that the certificate was so far false that it omitted a material circumstance, and that the Registrar-General had been asked, and had declined, to take any action in respect of such allegation; and (3) whether the Home Secretary would take steps either in regard to this particular certificate or generally to safeguard the accuracy of certificates of death.—Mr. Walter Long replied: My right hon. friend has asked me to answer this question. The reply to the first two paragraphs is in the affirmative. As regards the third paragraph, I have no authority to interfere in the matter, but I may state that the Registration of Births and Deaths Act, 1874, provides that any person who wilfully makes a false certificate for the purpose of the Act shall be liable to a penalty. There can be no doubt that the omission from the certificate of death of the fact that the deceased person died while under the influence of an anæsthetic is to be regretted; but I understand that the Registrar-General was not satisfied that the omission constituted a definite offence against the Act, and that under all the circumstances of the case he did not consider that any action could usefully be taken by him, more especially as the matter was not brought under his notice until eight months after the death occurred.

Troops in Hospital in South Africa.

Lord Stanley stated, in answer to a question, that the last report, dated March 8th, 1901, with regard to the number of troops in hospital in South Africa showed 13,993.

Tuesday, April 23rd.

Prosecutions for the Sale of Diseased Meat.

Mr. Field asked the President of the Local Government Board whether he was aware that a person charged with selling articles of food in contravention of the Sale of Food and Drugs Act must be informed of the exact nature of his alleged offence and of the alleged adulteration, as stated in the analyst's certificates, while persons charged with selling diseased meat under the Public Health Act, 1875, were not informed of the exact nature of the disease, but were vaguely charged with selling meat which was diseased or unsound or unfit for food; and, as under these circumstances the defendant could not prepare his defence, whether he would take steps to oblige sanitary authorities to state the exact nature of all such charges and medical officers of health to furnish to the person whose meat was seized a certificate of the exact nature of the disease affecting the meat seized.—Mr. Long replied: I am aware of the different requirements of the Sale of Food and Drugs Act and of the Public Health Act with regard to the matters referred to. I may point out that the adulteration of food and drugs can ordinarily be discovered only by the application of chemical tests. This is not so as regards meat which is diseased or unsound or unfit for food. The two classes of cases do not, therefore, seem to be parallel. I cannot say that I think that there is any sufficient ground for proposing such a change in the law as that suggested in the question.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Bramwell, E., M.B., C.M. Edin., M.R.C.P. Lond., has been appointed Medical Assistant, Edinburgh Royal Infirmary.

Burland, Herbert, L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Finedon District of Northants.

Chancellor, William, M.B., B.Ch. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Banbridge District of county Down.

Cusse, E., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Broughton District of Hants.

Davies, H. H., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Cerrig-y-Druidion District of Denbighshire.

Dwyer, F. C., M.D. Dubl., B.Ch., F.R.C.S. Irel., has been appointed Professor of Surgery, Royal College of Surgeons in Ireland, vice Sir W. Stoker.

Foster, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Walton-on-Naze District of Essex.

Giles, Arthur E., M.D., B.Sc., F.R.C.S., M.R.C.P., has been appointed Gynæcologist to the Hospital of St. Francis, New Kent-road, London.

Grace, Gerald, L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Middleburgh District of the Transvaal.

Grahame, Alex., M.B., B.Ch. Irel., has been appointed a Civil Medical Officer to the troops in South Africa.

Lindsay, James F., M.B., C.M. Edin., has been appointed Medical Officer for the prison, Dunblane, vice C. W. Howatson, resigned.

Macdonald, James H., M.B., Ch.B. Glasg., has been appointed Senior Assistant Medical Officer to the Govan District Asylum, Crookston, near Glasgow.

Pierce, R. W. C., B.Sc., M.B. Lond., D.P.H. Camb., has been appointed Medical Officer to the Guildford, Godalming and Woking [illegible]

[illegible] M.R.C.S., has been appointed [illegible] Factory Acts for the Warlingham [illegible]

Kirton.—On April 21st, at Ashville, Honor Oak [illegible] C[illegible]

Long[illegible] L[illegible]

Mac[illegible] B[illegible] Government Board, Ireland, of a son.

MARRIAGES.

Cooper—Day.—On April 17th, at St. Stephen's, Gloucester-road, by the Rev. F. W. Worsley, M.A., Charles Edward Cooper, B.A., M.B. Cantab., of Ivybridge, S. Devon, younger son of the late Joseph Cooper, of Colyford, Devon, to Fanny Elizabeth, third daughter of R. Newcombe Day, of Harlow, Essex.

Hulke—Hawkins.—On April 17th, at St. Barnabas's, Kensington, Sydney Backhouse Hulke, F.R.C.S. Eng., third son of the late Frederick Thomas Hulke, of Admiralty House, Deal, to Irene Beatrice, youngest daughter of Major General E. L. Hawkins, late R.A.

Mavor—Gower.—On April 16th, at St. Mary Magdalene's, Enfield, William S. Mavor, M.D., of Waltham-cross, to J. Lillias Gower, eldest daughter of the late Edwin Gower, of Theobalds, Waltham-[illegible]

[illegible] Christ Church, Pitsmoor, [illegible] Lond., M.R.C.S., L.R.C.P. [illegible] rd daughter of John James [illegible]

[illegible] Christ Church, Longcross, [illegible] Mabel Catherine, daughter [illegible]

DEATHS.

Bampfylde.—On April 22nd, James Bampfylde, M.R.C.S. Eng., L.S.A. Lond., D.P.H. Eng., aged 36, youngest son of the late Major Bampfylde of Bath.

Barclay.—On April 17th, at Sumner-place, S.W., John Barclay, M.D., F.R.C.P., aged 81.

Ogle.—On April 19th, at Charlestown, Natal, Arthur W. Ogle, M.R.C.S., aged 48.

Tanner.—On April 21st, at Reading, Charles Kearns Deane Tanner, M.D. Irel., M.P.

Tebay.—On March 25th, 1901, at Manoas on the Amazon river, S. America, Michael Kemble-Tebay, M.R.C.S. Eng., L.R.C.P. Lond., aged 30, only son of Emily and the late M. J. Tebay, M.R.C.S. Eng., L.S.A., of Woburn-hill, Addlestone, Surrey.

Watkins.—On April 21st, at Towcester, Edwin Thomas Watkins, M.D. (late R.N.), of Cambridge-gardens, Notting hill, W., aged 76.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE LEICESTERSHIRE SAMARITAN INSTITUTE FOR DISEASES OF WOMEN.

A CORRESPONDENT, who is a medical man, has forwarded to us the following circular which was sent to him. He informs us that he knows nothing of the presumable sender—namely, the practitioner whose name appears at the bottom of the circular.

"Leicestershire Samaritan Institute for Diseases of Women,
1A, Bowling Green-street, Leicester.

DEAR SIR,—I know how difficult it is (however willing one may be) to thoroughly examine and treat cases of uterine mischief that one may meet with on general practice. Lack of time prevents the busy practitioner taking up and treating many cases that would rapidly improve under appropriate local treatment; and the inadequate remuneration one receives for contract work of all kinds would not cover the cost of diagnostic instruments, let alone compensate for the time taken up in the work. Again, lack of material in the shape of uterine cases prevents many taking that interest in gynæcology which is essential to success. By sending such cases to an institute where they may be taken properly in hand the already heavy burden of the practitioner may be lightened. I inclose six free tickets for use at the out-patient department and venture to hope that you will make use of them in suitable cases. I have accommodation for a limited number of in-patients where operation is necessary. Yours faithfully,

JOHN SIDES D. MACCORMAC."

We cannot find the name of the above institute in the list of charities given in Burdett's "Hospitals and Charities," in the "Annual Charities Register and Digest," or in the list of provincial hospitals given in the "Medical Directory," so that we are unable to form any idea as to its status. But whatever this be we do not think it is fitting for a charitable institute to tout for patients in any way. More especially do we consider it most objectionable for the medical officer, or one of the medical officers, to act as tout and to write circulars to his medical brethren implying that they do not know their own business. The six free tickets, we observe, are endorsed with a notification that a sum of 1s. is charged for each visit to defray the cost of medicine, bottles, &c. Perhaps the secretary of the institution, if such official there be, will kindly send us a report of the working of the charity, if one is published. If there is no secretary and no report, possibly Mr. John Sides D. MacCormac will give us some further information as to the members of the staff, what are their qualifications, and what are their claims to possess gynæcological knowledge superior to that of the duly qualified general practitioner.

HOME NURSING.

To the Editors of THE LANCET.

SIRS,—I am about to deliver a course of six lectures on home nursing to the probationers and others at the hospital at which I am house surgeon. The syllabus will be that given in Caird and Cathcart's Manual—i e., 1, the Sick Room; 2, Infection and Disinfection; 3, 4, and 5, Details of Nursing; 6, Application of Local Remedies. Can you or some of your readers advise suitable books written on the above lines?

I am, Sirs, yours faithfully,
April 24th, 1901. H. S.

THE EFFECTS OF THYROIDIN.

To the Editors of THE LANCET.

SIRS,—Will some reader who has experience inform me where I can procure information on the subject of poisoning by excessive doses of thyroidin? The subject of inquiry took three tabloids of B. & W.'s preparation three times a day for 2—3 months. He suffered from intermittent pulse, from neuralgic pains in the loins, from loss of power in the legs (especially at night), and from intoxication after very small quantities of whisky (the intoxication affecting the legs only). It was taken with the idea of reducing weight and this it certainly achieved. The result was a reduction of two stones in weight (about), a feeling of *bien-aise*, and an increase of appetite. It has been given up for nearly two years with certain benefit, but not cure, the leg weakness persisting. There is also inability to take strychnia and other astringents. I have been advising the patient, but have not met with any literature.

I am, Sirs, yours faithfully,
April 23rd, 1901. K. E. M.

THE CERTIFYING OF STILL-BORN CHILDREN.

ON April 16th Mrs Nora Lunn appeared before Mr. Paul Taylor at Southwark Police-court to answer a charge of wilfully and falsely making a declaration under the Births and Deaths Registration Act of 1874 to the effect that a certain child born alive was still-born, knowing that such declaration was false. The defendant pleaded guilty but said that she did not know that she was doing wrong. This was her first offence. The child lived barely an hour and the mother was anxious not to lose the parish relief. Mr. Paul Taylor fined the defendant £10 or in default six weeks imprisonment, saying that for a midwife to give a false certificate might lead to crime upon a wholesale scale. We quite agree with the magistrate's remark and in addition we consider that it is a perfect scandal that midwives should be allowed to give death certificates at all. The whole system of death certification is in a hopelessly unsatisfactory condition and the present laws dealing with the system need to be revised. We must confess that we do not understand Mrs. Lunn's remark about parish relief. Surely in Southwark parish relief is not granted to anyone having a still-born child. If so it seems to us to be a premium upon murder. If it is not so Mrs. Lunn's remark has no meaning.

"THE TREATMENT OF THREAD-WORMS."

To the Editors of THE LANCET.

SIRS,—In reply to the letter of "Worms" in THE LANCET of April 20th, p. 1179, I recommend him to administer balsam of copaiba (about seven minims) three times a day either in capsules or as a mixture with a small dose of castor oil two or three times a week. In the course of a fortnight he will, I think, have no reason to regret the trial. By this time probably no living worms will be passed. Solution of the perchloride of iron should then be given.

I am, Sirs, yours faithfully,
Wanstead, N.E., April 23rd, 1901. FRANK ABGLES.

"MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB."

AMOUNT already announced, £359 9s.

Honorary treasurers: Sir Charles A. Cameron, C.B., 51, Pembroke road, Dublin; and Mr. L. H. Ormsby, Vice-President of the Royal College of Surgeons in Ireland, 92, Merrion-square, Dublin. *Honorary* Secretary: Mr. George F. Blake, Royal College of Surgeons, Dublin. As the list must shortly close intending subscribers should send in their subscriptions as soon as possible.

INSTANTANEOUS PHOTOGRAPHY.

MR. EDWARD F. GRÜN, M.R.C.S. Eng., has recently succeeded by means of a special lens of his own invention in taking photographs of stage performances from the auditorium by ordinary stage illumination. The lens is said to be 50 times faster than any yet made. He has sent to us a specimen print of a scene from *Floradora*.

"THE CASE OF MR. LOUIS FERDINAND DODS: AN APPEAL."

To the Editors of THE LANCET.

SIRS,—On behalf of Mr. Dods I beg to thank you for inserting his appeal in THE LANCET of April 20th, p. 1161, and for your most excellent annotation, p. 1153. At the request of Mr. Walsham, the honorary treasurer of the fund, I now beg to send you a first list of contributors. Contributions may be forwarded to Mr. W. J. Walsham, 77, Harley-street, W. Cheques to be crossed London Joint Stock Bank Limited.

I am, Sirs, yours faithfully,
London, April 24th, 1901. JOSEPH E. S. KING.

H. J. H.—The organisation of the hospital fits it to be a training school for nursing probationers, but the number of beds is small. Our correspondent will find the subject thoroughly dealt with in Sir Henry Burdett's book, "The Nursing Profession; How and Where to Train."

India Rubber (Manchester).—If our correspondent will consult his usual medical attendant he will be able to procure all the information he needs about the watering-place in question.

A. M. S.—We do not give medical advice.

During the week marked copies of the following newspapers have been received:—*Manchester Courier, Birmingham Post, Surrey Times, Scotsman, Eastern Daily Press, Londonderry Gloucester Journal, Halifax Courier, Western Times (Exeter), castle Chronicle, Norwich Eastern News, Herts Advertiser, Advertiser, South Wales Echo, Manchester Guardian, Herald, Western News (Plymouth), Baptist, Court News, Standard, Lancaster Guardian, Bridge of Allan Gazette, Post, Grimsby Gazette, Weekly Free Press and Aberdeen He Wolverhampton Weekly News, Callander Advertiser, North (Darlington), Kentish Observer, Daily Chronicle, Times of I Pioneer Mail, Citizen, Builder, Architect, Reading Mercury, Government Chronicle, City Press, Hertfordshire Mercury,* *Journal, Sligo Independent, Local Government Journal, Surrey Advertiser and Standard, Weekly News Budget, Royal Cornwall Gazette, Hong-Kong Telegraph, Clifton Chronicle, South African News, Manchester Chronicle, Windsor Chronicle, Malvern Gazette, Weekly Times, Essex Newsman, Worksop Guardian, People's Journal (Forfar), Doncaster Chronicle, Bury Free Press, &c., &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Ad tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Clinical Lecture

ON

ECZEMA IN RELATION TO AGE.

Delivered at the Medical Graduates' College and Polyclinic on Jan. 9th, 1901,

BY MALCOLM MORRIS, F.R.C.S. EDIN.,

SURGEON TO THE SKIN DEPARTMENT AT ST. MARY'S HOSPITAL, AND LECTURER ON DERMATOLOGY AT ST. MARY'S HOSPITAL MEDICAL SCHOOL.

GENTLEMEN,—Heinrich Heine the poet, when he was on his "mattress grave" suffering from a terrible form of paralysis, used to spend a part of his time in reading medical books about his disease, and, according to Matthew Arnold, one of his friends asked him one day what advantage he supposed this reading would be to him. His answer was that he was preparing to give a lecture in heaven as to the want of knowledge of the doctors on this earth concerning the diseases of the spinal marrow. I think that if Heine were alive to-day and suffered, as he might suffer, from a terrible attack of eczema, with all its tortures and its frightful irritation, he might study the works which are published at the present time and might have given the same answer. The painful truth is that what he said about spinal diseases might equally be said about this particular disease. The various books and papers which are published upon eczema differ enormously in almost all particulars concerning the disease. There are hardly two of them that agree even on a definition. Is it, therefore, to be wondered at that the disease is an exceedingly difficult one to understand? In the whole range of dermatology, as far as my experience goes, there is no subject which at present more eludes our mental grasp than the pathology and treatment of eczema. This statement will doubtless sound discouraging, but we must look the truth in the face, otherwise no progress is possible. Those who have devoted their lives to the work, who have been studying eczema for years, still find the same difficulties that others have found before them. There are difficult points that arise and meet us at every phase of the disease, from the beginning to the end. In my remarks to day I propose to take certain of the commonest forms, those common types which every practitioner meets in his daily work. I do not propose to go into the various theories of eczema or to discuss problems in connexion with them; these are better discussed at congresses, international or otherwise. I would ask you to imagine that we are actually at the bedside of a patient and that we are confronted with problems which we have got to try to solve; the various difficulties that meet us we will discuss in detail according to the different forms The first thing which has to be recognised is that this disease presents certain well-marked differences corresponding to different ages in life I shall divide the subject in this way: (1) the eczema of the infant; (2) the eczema of the young child; (3) eczema at the age of puberty; (4) eczema in the adult; (5) eczema in the adult woman at the change of life; and (6) eczema in the aged.

ECZEMA IN INFANCY.

First, with regard to eczema in the infant We will suppose that the practitioner has attended a woman in her confinement, and that after the child is born the nurse calls his attention to the fact that there is a little circular patch on the scalp. The patch is generally of about the size of half-a-crown, or a little bigger, of a dirty-brown colour, and composed of greasy material which is very adherent to the scalp. The nurse asks what is to be done. The usual answer, or at any rate a very common answer, is that it is of no consequence—that it is nothing, and that it will disappear in the course of time. This little patch is a patch of seborrhœa; sebaceous matter has been secreted and has dried. This little patch is of the greatest possible importance, and it will therefore be well if the practitioner pays considerable attention to it. It is very often the focus from which an eczema of the scalp in an infant will start. The first thing that happens if it is left alone is that around the brownish patch in the centre of the scalp a red areola appears, and from that red areola other circular patches will appear on other parts of the scalp. Now if care is taken to treat this in the very earliest stage I believe that a considerable amount of eczema in the young child will easily disappear. The question is how it should be treated. We have first of all to recognise the fact that in the child there is a great blood-supply to the brain. It is necessary that this should be so, as abundant nutritive material is required for the formation of bone and the building of the brain. Owing to the great vascularity of the scalp the slightest irritant is very likely to convert what is in the first instance a trivial condition into a very acute one and to make the eczema spread from that particular spot. As a rule nurses are very fond of scrubbing the infant very freely with soap-and-water. I think that is much overdone, and I think a word of warning should be uttered by the practitioner, especially if the child has the slightest sign of irritation of the scalp. Washing should not be done with any violence. If a soap be used it should be a superfatted one; it should not be the ordinary yellow soap The scaly material should be treated with the greatest possible gentleness and should only be removed by degrees

Next, should the child's head be kept covered? I think infants' heads are kept far too much covered; and if there is the slightest tendency to any inflammatory condition of the scalp it is better that the child should not wear any form of cap, especially in the house, and when taken out should not be too warmly clad about the head. Friction tends to increase the blood supply and to cause irritation. If the patch of eczema does not disappear it will go on to a more acute condition and will spread in the form of circular patches, not only on the scalp but also on the face. Thence it will come down the front of the chest, and it may pass down behind the ears and so down the neck, and in that way there may be a complete collar formed round the neck Then patches may appear upon the abdomen and the back and subsequently on the limbs. These patches may be red, slightly raised and scaly, and to a slight extent irritable But after a time the disease will suddenly assume an acute character and will pass from the first dry red stage into an exudative stage and there will be discharge. In parts there may be actual vesication or pustulation. It is in a young child that eczema tends more especially to become pustular. In a certain number of days—or it may be hours—the discharge will dry and form crusts, and then the typical condition of eczema of the infant will be met with, with thick crusts all over the scalp and face and scattered about the body. In the later stages there is a considerable amount of irritation. In the case of the adult it is often explained that the eczema spreads by means of scratching, but this cannot be so in a small infant which has hardly strength enough to scratch; therefore there must be some other explanation why these patches spread. Many mothers are often in the habit of tying infants' hands or of enveloping them in bags so as to prevent their scratching themselves. I think it is a wrong and cruel thing to do. If I had an eczema I should not like to have my hands tied or enclosed in bags and I do not see why the defenceless infant or young child should be so treated It must be our endeavour so to modify the process that we can give the child relief without putting it to that extra torture

As regards the treatment of this form of eczema in the first stage, when it is only in circular scaly patches, it is to my mind purely a local condition and requires no constitutional treatment at all The local treatment should be of the very simplest and gentlest character; strong ointments or lotions are not appropriate. The applications should be of an antiseptic character. There is no better one, especially in the first instance, than an extremely weak sulphur ointment—five grains of precipitated sulphur to one ounce of benzoated lard When the discharge stage begins it is necessary to consider what particular factor it is that has converted the simple patchy, dry form into an acute condition That is one of the greatest problems connected with the subject. Every practitioner has his own views on this particular point The probable answer to the question is that it is a complex factor or several factors which produce the change from the simple seborrhœic condition to the acute eczema in the infant. One of the first causes always alleged is that the child is improperly fed, but I have seen eczemas commence and become extremely severe, and go through their other phases and relapse though the child has been fed in every way properly, when it has been taking its mother's milk and the mother is in good health. Therefore, that particular factor at that time need not necessarily be the cause of this sudden change. It is possible that there is something inherent in the skin itself which causes the change, but what that is is an unknown x, something which is added to the original condition which converts it from a quiet stage into an acute discharging one. But a little later, as the child gets older, there are factors which unquestionably have an influence. The first of these is vaccination. We are constantly asked what is the relation between vaccination and the eczema of infants. Now, the usual rule with vaccination officers is that they are not to vaccinate a child who has eczema. What is the reason of that rule which, I believe, is one of the regulations of the Local Government Board? The chief reason is that the vaccination will not take if there is a discharging surface. So that in the acute condition vaccination is not appropriate simply because the vaccination will not take. In some rare instances the acute stage is shortened and moderated by it and the eczema dries up and disappears, apparently under the direct influence of the vaccination. On the other hand, if vaccination is done when there are only circular scaly patches of the seborrhœic type and nothing acute the vaccination as it comes to its height with the fever which is produced will rouse these patches into a state of violent inflammation. This rarely occurs, but it does occur and it ought to be recognised at its true value. Not only will vaccination do it, but other zymotic diseases will. It is not at all an uncommon thing for a child with scaly, dry patches to have them suddenly aroused into activity by an attack of measles. I have seen many such cases. There are other factors which are also irritating and which do harm in a reflex way. One of the commonest of these is intestinal worms. Young children with worms will have their eczema aroused into a state of the greatest possible activity, and it is necessary, therefore, that we should direct our attention to that. If, therefore, we have got a child who is being well fed, who is having food which is appropriate, and in whom the simple, dry, scaly condition has been converted into an acute eczema, what internal treatment can we give which is likely to modify the process and to relieve the symptoms? I believe there is no drug or combination of drugs which has such a good effect internally as mercury in some form. I believe it to be the experience of every general practitioner that if children are out of sorts a small dose of mercury will do wonders for them. Certainly that is the case as far as acute eczema is concerned. Of all the preparations of mercury there is none better than a small dose of calomel. It should be given at bedtime and repeated in two or three nights. So far as the constitutional treatment is concerned it is the best that I know for this condition.

Then as regards local treatment of the acute stage, it is first necessary to do everything in our power to dry up the discharge, and the best way to do that is to apply powder. But if powder be applied to the skin a crust is formed which is sometimes exceedingly difficult to get off, and in the process of trying to get it off the condition is again aroused into activity. Therefore, it is not a bad plan to apply the powder in a muslin bag. Then comes the question what particular kind of powder should be employed—whether it should be simply starch or rice powder, or whether it should be some antiseptic powder. I think that the best way out of that difficulty is to mix them. One part of finely triturated boric acid and one part of starch, and perhaps one part of oxide of zinc, should be taken. These combined make an exceedingly useful drying powder. If it is put into a muslin bag, not too tight, and loosely applied over the head, that will tend to moderate the discharge. Immediately after that something extremely soothing should be applied to check as far as possible the formation of scabs. One of the prescriptions which I am fond of using at that particular stage is what I call "zinc cream." It consists of oxide of zinc, lanoline, olive oil, and lime-water. The proportions best suited for it, I think, are: seven drachms of oxide of zinc, one drachm of lanoline, one ounce of olive oil, and one ounce of lime-water. It will at once be seen that the olive oil and lime-water make carron oil, to which are added oxide of zinc and lanoline. If oxide of zinc be added to the carron oil without the lanoline a separation of the lime-water is obtained which interferes very much with its efficacy. As regards its preparation, the best plan is to mix the olive oil and the lanoline together in a bath, and when it is melted add the lime-water, and then while it is still warm stir in the oxide of zinc. If that is done in rather a large way, and the ingredients are therefore thoroughly mixed, the blandest possible cream will be the result. We know how in the case of burns the carron oil relieves the smarting and the pain, and as we want to do that in this condition it is a particularly useful application for it. To that cream can be added drugs of an antiseptic character, and there is none that I know of that irritates less or answers better in drying up this condition and converting an acute into a subacute stage than ichthyol. A very small quantity should be used. In infants I would begin with half a drachm of ichthyol to three ounces of the cream. Then with regard to the way of applying it. Linen should be torn into narrow strips and should be soaked in this cream and then applied very accurately. The whole of the affected skin surface should then be covered with a very thin gauze bandage to keep it in place. As soon as it begins to dry these strips should be removed and some more should be dipped into the cream and applied as before. As soon as the condition passes into the dried-up scaly stage an ointment is more suitable than the cream, because the cream is exceedingly drying in its effects. Then we come to the use of a simple ointment. I would here say that it is a very common thing to use simple boric acid ointment for it. That is about the most uncertain application I know of. Sometimes it is of use, but sometimes it irritates badly and does an immense amount of harm. On the whole it is too uncertain to trust to in young children. At the next stage, therefore, I suggest weak ammonio-chloride of mercury ointment.

This form of eczema, like all others, is cyclical in its nature. It starts in the way I have described; it comes to its height and then subsides again; but the whole tendency of the condition is to commence again; and in spite of all our treatment, however well directed it may be so far as internal or local treatment is concerned, there are a certain number of cases that go on relapsing again and again, and I do not know of any method of treatment by which these particular cases can be certainly cured. Fortunately the proportion of these stubborn cases is exceedingly small. We know that some adults who are the victims of constant attacks of eczema will tell you that they have had it since they were infants. The disease may become altered in character to some extent when they get older, but still it is clear that if they have been told that they had it when very young it has persisted more or less all through their lives. As I say, in spite of all the schemes which have been suggested, I know of nothing that will ensure non-recurrence. But if we are very careful in the matter of treatment we can reduce the number of those incurable cases to a very small percentage. Accuracy of treatment in early life I believe to be the key of a great deal of the success in future. Individuals may be saved from becoming eczematous subjects in later life if sufficient care with regard to the conditions in infancy and in childhood be observed.

In the more chronic forms of eczema in infancy, when it is not expedient to be constantly giving calomel, small doses of grey powder given as an alterative every night for a time seem to modify the process. I do not think that there is any use in giving very young children alkalies or in attempting to give them so-called specific treatment. Indeed, I know of no drug which can be called specific for the disease, therefore I think I should treat it on general principles as I have indicated rather than attempt a course of arsenic.

ECZEMA IN CHILDHOOD.

Now we will pass on to a little later in life—that is to say, to a child of four, five, or six years of age. Such a child may not have had eczema as an infant. At such an age the disease is also generally of the seborrhœic type. It usually begins with the formation of circular or oval patches of a rough and scaly character upon the cheeks or forehead. These patches are usually passed by as being of no consequence. But here, again, I would urge that they are of great importance and that they should be treated. They are easier to treat when they are quiescent than when they are acute, and a relapse is much less likely if the original scaly condition be treated at the beginning. At this age the question occurs whether a child who is liable to repeated attacks of eczema of this character should go away to school, or whether such child should go to the seaside for the benefit of the general health. First, with regard to going away to school, I think children who have a tendency to this disease are far better treated at home; they are generally under the care of their mother, and are more likely to get well under these circumstances than if they were under the care of strangers I have seen disastrous results from children with a distinct tendency to relapses of eczema going to school With regard to the question of benefiting the general health by going to live at the seaside so as to get rid of this tendency, perhaps the patient has passed through the acute attack, but the parents have had experience of so many attacks in the past that they will ask the medical attendant if the child should be sent to the seaside. The answer depends entirely upon the character of the eczema. If the eczema of early life has left behind enlarged glands, which it may do from the local irritation, and if there is a distinct tuberculous history in the family it is in some instances a particularly wise thing to send the young child to the seaside. I have seen many children who have lost their glandular enlargement, who have got perfectly strong and well, and who have at the same time lost their tendency to relapses of eczema by residence by the sea On the other hand, if the attacks are inclined to be extremely acute then certainly it is not wise to send the child to the sea, especially if there is no enlargement of glands and if there is nothing to suggest the possibility of a tuberculous history.

The next point which I want to deal with is the relation of eczema to teething It has been the custom of the profession to be perfectly certain that teething is answerable for these attacks It has never been perfectly clear in my mind that this is true I have seen some of the worst cases before the teething period ; I have seen some of these children who have been well during the teething period and have been very bad afterwards, so I am doubtful as to what relation teething has to it But the feeling is very strong, and I think the bulk of the profession would say that there is a strong influence in teething.

ECZEMA AT PUBERTY.

There are two chief form of eczema which may commence at puberty One is the seborrhœic form, which may commence upon the scalp and may also attack the face and other parts of the body, apparently by local infection, and the other is the form which is associated with dry skin—xeroderma It is, as a rule, about that time of life that the first signs of eczema occur in connexion with xeroderma In early life it is hardly noticeable ; the skin is usually soft, but as the child gets older, and especially when it comes towards puberty, the skin becomes dry and harsh and a particular form of eczema is associated with it It is not necessarily the result of exposure to cold or to cold winds, but it will come notwithstanding every possible care when the child is not exposed to bad weather. It usually attacks the flexor surfaces—the bends of the elbows and knees This form of eczema requires rather a different kind of treatment from that which occurs in young children. It is essential that the dry condition of the skin should be treated, and this is to be done by emollient baths—that is to say, by soaking the skin in a prolonged bath, and then by softening the dry hard parts by means of glycerine and water in the proportion of five parts of water to one of glycerine This should be well dabbed over the parts which are dry, and it will enable the parts which are inflamed to heal under very simple applications If the eczematous patches are very acute the zinc cream already mentioned, with the addition of some antiseptic, will probably be enough to heal them, but no treatment will be effective unless attention is directed to the xerodermic condition of the skin as a whole

There is another type which at this time of life very often appears for the first time, and that is the form of eczema which alternates with nerve-attacks, more especially with asthma and with the commencement of rheumatoid arthritis When asthmatic attacks are severe it is not uncommon for the eczematous condition to disappear, and *vice versa* when the asthma is quieted the eczema is often bad Again, it is not uncommon for pains in the joints to alternate with acute eczema This group requires special internal treatment. Certain nerve tonics, such as valerianate of zinc, small doses of quinine, and if the case is a very bad one perhaps even small doses of opium, should be given to quiet not only the asthma but also the recurrent attacks of eczema

ECZEMA IN THE ADULT.

Now we pass to a consideration of eczema in the adult. First I would call your attention to a severe general attack of eczema in an otherwise perfectly healthy person ! You may meet with an individual who has never had eczema before and he is in all respects perfectly well. He is suddenly exposed, we will say, to extreme cold. He may have ridden on the top of an omnibus and have become extremely chilled when returning home in the evening ; he may perhaps have had a trifling rigor and next day he will show signs of eczema on various parts of the body This eczema will sometimes come out suddenly so that in a few hours the whole of the body may be attacked by it Especially does it attack the more sensitive and tender parts of the skin—the flexor surfaces of the arms, the backs of the legs, the chest, and the back. I have seen a person become covered all over with discharging eczema in 48 hours after exposure to severe cold In such a case the patient should be put to bed and be covered over with the lightest possible clothes ; his diet should be of a very non-stimulating character, without alcohol or coffee or tea ; and the bowels should be opened by a dose of calomel, followed by a saline in the morning As a remedy I know nothing which is of greater use than small doses of tartarated antimony. This is the particular form in which antimony is of the greatest possible service. It should be given in repeated doses at first ; the second dose should follow an hour after the first, and the third dose three or four hours afterwards, and following that three times a day. A thirty second of a grain is quite enough to produce a marked effect. Here I should like to relate briefly the actual facts of a case illustrating this type of the disease. The patient was a man about 43 years of age, in perfect health, who had never had an attack of gout in his life, who had never had rheumatism or any serious disease except the ordinary diseases of childhood, such as measles, and who had never had eczema One day he went out for a drive in his carriage, apparently in perfect health. When he returned from that drive he told his wife that he felt ill and thought that he had caught cold. Next day he had an acute general eczema over the whole of his body I saw him in consultation on the following afternoon, exactly 24 hours from the time he went for the drive and he was discharging practically from every part of his skin. Now, such an acute attack as that could hardly be explained, I think, by the action of microbes on the skin. I think that the only possible explanation is that it was a sudden nerve storm, a neurosis which took this particular form. Instead of getting a sudden attack of bronchitis or of catarrh he suddenly got a catarrh of his skin. That night he was given four grains of calomel and a saline on the following morning. At 4 P.M. or 5 P.M. a dose of a thirty second of a grain of tartarated antimony was given, and that was repeated again in three hours. The only local treatment he had was that he was put to bed and was powdered all over with oxide of zinc and boric acid. I saw him again on the following afternoon, when there was no discharge whatever ; the parts were absolutely dry and he was covered all over with crusts and scabs as a result of the drying up of the discharge. He had had a very free action of the bowels as a result of the calomel and the saline in the morning, and in every way he expressed himself as being very much better. He went on with the antimony for four days afterwards. When I saw him again at the end of that time all signs had gone except that though there was practically nothing to be seen he was left with the most severe irritation of the whole of the skin. That is, perhaps, one of the most troublesome things which practitioners are called upon to treat—namely, the irritation left behind from a very severe acute attack. The intense dread of another attack coming on produces a state of great nervous excitement Though there is nothing to be seen these patients will scratch and suffer terribly from the irritation, so much so that in some cases it produces a disturbance of the nervous system almost amounting to actual insanity. In the particular case which I have mentioned the man's irritation was fearful, and he said that it was then worse than on the day when the attack was at its height. That was treated for weeks with all kinds of local applications, but nothing whatever did him the slightest good Applications of weak tar and many other remedies were applied, but he did not get any relief from his itching until he went to Schinznach in Switzerland, where he had a course of baths for three weeks He returned free from irritation.

Perhaps this is the place to emphasise the importance of the mineral water treatment in certain forms of this disease.

It is not appropriate to send persons to a mineral water cure during the acute stage, nor is it appropriate to send them during the subacute stage which may follow; but it is appropriate to send them when they are left with only a neurosis as the result of it. I do not say that that is the only form of eczema which is benefited by mineral water treatment, but I think that it is one of the most important.

Eczema and alcohol.—In connexion with general attacks I think a word should be said about eczema and alcohol. I have recently had a case under my care which has brought this prominently before my mind. A man in active business had been in the habit of taking a very fair quantity of alcohol every day for a great number of years, though never in excess. He was suddenly laid up with an acute attack of eczema. He was treating himself for a length of time before he called in his medical attendant, and during that time he was continuing his alcohol Afterwards the alcohol was stopped, and under simple treatment he got well. When he went back to his work he began to take his alcohol as before, and had a second attack of eczema. It was then suggested to him that he should leave off taking alcohol altogether He did so and has not had a return since. I think the relation of alcohol to these attacks is a very important one

Intertrigo.—The next form, which is very common, is the form known as intertrigo, the attacks of eczema which occur round the scrotum and on the inner side of the thighs and about the anus. It usually commences with a circular red patch at the upper and inner side of the thigh, and from the pressure of the scrotum against that patch a corresponding patch will come upon the scrotum. After a little time the patches will spread, and will extend backwards, and will very likely come upon the other side, until at last a red irritable patch will be formed more or less corresponding to the bathing drawers area, spreading up over the abdomen as high as the umbilicus, and then up the buttocks behind. This is an exceedingly painful and irritable form of eczema. It usually occurs in people who take a considerable amount of exercise and sweat freely in that part. In that case it is necessary to curtail the exercise and not to let the patient walk too much. If the condition is very acute or very painful and there are cracks between the scrotum and the thigh the patient should be told to rest for a time in bed. The parts should be bathed freely with an antiseptic lotion and then carefully dried, and an ointment containing a small proportion of sulphur should be applied accurately all over the parts. It is not necessary in this form to give any internal medicine. It is purely local and requires local treatment for its cure.

Varicose eczema—The next form, which is exceedingly common in adults, is the form which is associated with varicose veins, namely, varicose eczema. It commences, as a rule, in a single circular patch, which spreads at its edge. There is usually some discharge and the part becomes exceedingly painful, and perhaps it will prevent the patient from walking. In the course of time it may lead to a varicose ulcer. The treatment is rest in bed, with the leg elevated, especially at night, and the application of an exceedingly useful preparation—namely, Unna's zinc glycerine jelly. I do not know of any application of more use for this particular form of eczema. It is made by mixing oxide of zinc, gelatin, glycerine, and water. It can be got from almost any chemist and the way to apply it is rather important. The little cube should be placed in a galley-pot which is dry; the galley-pot is then placed in a pot of boiling water until the gelatin liquefies. As soon as it liquefies the pot should be taken out of the hot water and allowed to cool a little. As soon as it is sufficiently cool to be put upon the skin it should be painted on by means of a large brush. It is important not to move the brush up and down and from side to side. The brush should always be laid on in one direction, preferably from above downwards, beginning with firm pressure. One single application is enough for any one area. It is not suitable if there is much discharge. The gelatin should be applied all over the vein as well as over the eczematous patch. As the gelatin is drying a little cotton-wool should be put upon it so as to make it dry. Then the patient can put on a sock and drawers and he will remain perfectly comfortable. Usually, if the condition of the skin is not too acute, one application will last three days. It should then be taken off, without the application of water, being peeled off like a kid glove. After washing the skin with an antiseptic lotion such as weak carbolic or tar the gelatin should be re-applied. It is exceedingly useful because it enables a patient with that form of eczema to go about his business. It is also applicable to other forms on other parts of the body. It is particularly useful for the trunk, for the back, and for the chest.

Chronic eczema of the leg.—There is another form of the disease which is exceedingly common which practitioners are constantly called upon to treat—namely, the small circular chronic patches which are usually seen upon the leg. A man may have a little patch which he has had for years. He may have no varicose veins and perhaps it has been his habit every day after his bath to scratch this patch. But all of a sudden, for some reason, it becomes acute and may spread rapidly all up the leg, perhaps also over the body. That is the form which authors have called attention to for many years and it is one that I think is of the greatest possible importance—namely, chronic patch on the leg in middle-aged people. A serious effort should be made to try to get rid of the patch. I saw a practitioner to day who had got an extremely irritable patch about two inches above the outer side of his ankle. He told me that he had had it for years and that he was constantly rubbing it with the other leg, or he scratched it after his bath. I put the drugs which are efficacious for it in the following order: salicylic acid, resorcin, pyrogallic acid, and chrysarobin. These are used in the form of an ointment. I should begin with salicylic acid, 10 grains to the ounce. If that failed I would combine resorcin with it, 15 grains to the ounce. If those two drugs failed I would use pyrogallic acid ointment, five or six grains to the ounce. If, after making the pyrogallic acid stronger it still failed, I should try unguentum chrysarobini of the British Pharmacopœia, but of half strength. The ointment requires to be well rubbed in, and a little should be left on the surface and the parts should be covered with linen and a bandage should be applied. I must leave out many things because time will not permit me to deal with everything.

ECZEMA AT THE MENOPAUSE.

Let us now pass to eczema at the change of life. There are two special forms of eczema which occur at the change of life—and I am taking what I consider to be the commonest, those which come most before practitioners The two forms at this stage are acute eczema of the head and face, which Jameson says are 75 per cent of them. As regards that particular type it comes at the change of life—that very variable period which may extend almost to any length of time. We do not know exactly when the nervous influences of change of life begin; they may begin as early as at the age of 40 years or even earlier. In those women who have had their ovaries removed all the phenomena of change of life are produced prematurely. I have recently seen a woman of only 26 years of age, who has had both ovaries removed, who has had all the phenomena of change of life just as if she were 48 or 50 years of age and who is suffering from the skin troubles associated with that period. There is usually considerable flushing, sweating, and other nervous phenomena, headaches, and disturbances of the digestive tract—dyspepsia and constipation. A spare woman at that time of life suddenly begins to flush in the face, perhaps after taking a meal; later the disorder becomes a little more acute; she gets an acute eczema of the scalp and it spreads down all over her face. For that condition there is no drug or combination of drugs as far as I know which is of such service to relieve the symptoms, not only the eczema but all the symptoms mentioned, as ichthyol. If it is used in the right way it is an invaluable drug, and this is one of the diseases in which it is of the greatest possible use. It is a nasty-smelling drug, therefore every attempt should be made to disguise the odour. If it is given in the form of Burroughs and Wellcome's tabloids, which are covered with sugar, there is no difficulty on that score. It can be given in tabloids covered with keratin which does not dissolve until it gets into the intestine, the result being that the patient does not get eructations of the ichthyol. The doses should be two and a half grains to begin with after each meal. At the end of two or three days it should be increased to five grains, then to seven and a half grains, and then to 10 grains. If the patient tastes it much the stomach has got more than it can digest. In that case the dose should be cut down a little But the effect of the drug in clearing away the symptoms is very extraordinary.

With regard to local treatment, this form of eczema which occurs at the change of life requires rather more active treatment than is needed at any other time. Such cases usually bear fairly strong applications of sulphur and resorcin.

The other form at change of life is the very acute eczema which occurs about the vulva and anus.

ECZEMA IN OLD AGE.

There is a particular form of eczema in old people which is very serious. First of all, as the result of enfeebled vitality old people get an atonic condition of the skin, and with this a form of chronic eczema with short acute exacerbations which does not disappear in the way in which it does in earlier life. In the aged it may worry the patient nearly into madness by the constant irritation, which, in Macbeth's phrase, "murders sleep," prevents the patients from taking their food properly, and so wears them out. Professor Kaposi has called special attention to this matter of interference with the taking of nourishment. He says that the disease produces a vicious circle in this way: As the result of constant irritation and inflammation of the skin there is a reflex irritation of the intestines which prevents the food from being properly digested. The action of the bowels being irregular it reacts upon the condition of the skin; there is thus a reflected condition from one side to the other. Whether it is absorbed from the skin and so into the blood it is impossible to say, but at all events their sufferings reduce these unfortunate people to the most dreadful condition, and it is not at all an uncommon thing for old people to commit suicide on account of their eczema. I have met with several cases of the kind. There is one drug for it, and only one as far as I know, and that is opium. As some philosopher has said, it is the drug of the aged, and we must not be afraid to use it. It is too much the fashion nowadays to be afraid of opium. If it is given at the right time it is one of the most valuable remedies, and the right time is past middle age. If aged persons do acquire the opium habit what harm is this likely to do them? They have not long to live in any case and the drug may make their few days less evil than they would otherwise be. I have recently had a most striking case of a very old man who was brought up to me from the country by his medical attendant. The man's life is intolerable. What is to be done for him? I have had a letter from the medical man, saying: "The remedy which you have given to my patient is of the greatest possible assistance." It was one-third of a grain of opium three times a day. He has taken it for some weeks; and if he continues to take it to the end of his life what harm can it do him? If it interferes with the action of the bowels that effect can be counteracted by aperients. If we cannot cure the disease it is surely something that by means of opium we are able to give the sufferer relief from a condition which makes his life a burden to him.

THE ACTION OF ARSENIC AS OBSERVED DURING THE RECENT EPIDEMIC OF ARSENIC POISONING.[1]

BY SIR T. LAUDER BRUNTON, M.D. EDIN., F.R.S.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

IF I may be permitted to give a short account of the general action of arsenic upon the body I think I may be able to classify the symptoms observed in the present epidemic of arsenical poisoning so as to render it easier both to remember them and to understand the varieties which have been described. Arsenic belongs to the same chemical group as nitrogen, which not only constitutes nearly four-fifths by volume of the atmosphere, but is an essential ingredient of all living tissues, and may be called the pivot on which all life turns. Other members of the group are phosphorus and antimony, both of which have an action very much like arsenic in many respects, and phosphorus, like nitrogen, is an important constituent of the healthy body. It is not certain whether arsenic acts by replacing nitrogen or phosphorus in the living tissues, and especially in protagon, which is one of the most important constituents of nerves, but it appears to have the power of altering the chemical changes or metabolism which occur in them during life and on which their functions depend. In minute doses it appears to be beneficial, but in large doses it is poisonous and will destroy both animal and plant life, so that in large quantities it will produce in man or animals irritation and inflammation of any part of the body on which it may be applied. This application may be made directly to a part or the arsenic may reach it through the circulation. Thus arsenic, when it is swallowed, reaches the stomach and intestines by direct application, and by irritating them produces vomiting and purging. In the form of dust, as from wall-paper or in making artificial flowers, it may enter the eyes, nose, and air-passages, and thus it may produce conjunctivitis, nasal and respiratory catarrh, and cough; or it may be applied directly to the skin and cause irritation and eruptions upon it. If much diluted it may produce little or no local irritation of the stomach, intestines, or respiratory passages, but from these it may be absorbed by the blood and carried by the blood to every part of the body. When absorbed from the stomach and intestines it is obliged to pass through the liver before it can enter the general circulation, and consequently the largest amount of arsenic is usually found in this organ after death from arsenical poisoning. Whilst circulating in the blood it may act on the heart, muscles, and nerves. But it is not carried by the blood only to these organs, for through the circulation it goes a second time to the stomach, intestines, respiratory passages, and mucous membranes of the eyes and skin. By these organs it is eliminated, and during the process of elimination it may again give rise to irritation in them just as it would do if directly applied. Moreover, John Hunter, Sir Everard Home, and Sir Benjamin Brodie have shown that when arsenic is applied to a wound it produces more violent and more immediate inflammation of the stomach than when the poison is administered internally and that this inflammation of the stomach precedes any appearance of inflammation in the wound.[2] Brodie concludes that "it may be inferred that arsenic, in whatever way it is administered, does not produce its effect even on the stomach until it is carried into the blood." This conclusion is perhaps too sweeping and not strictly true for arsenic in large doses and in a concentrated form, but it is probably quite correct when the poison is taken in moderate or small doses and in a diluted form, as in the beer at Manchester. Whilst circulating in the blood arsenic is carried to every organ and tissue of the body, and affects markedly the nervous system and muscles, the mucous membranes, and skin. It begins to be eliminated by the kidneys within a few minutes of its absorption and is also eliminated by the mucous membranes and skin. If only small doses are taken daily the whole of the poison may probably be daily eliminated, and it may be taken for months without any harm. But if the doses are larger less is eliminated daily than is absorbed, and it becomes stored in the body and produces symptoms of poisoning. During the process of elimination it irritates all the mucous membranes and the skin and produces corresponding symptoms. By irritating the mucous membrane of the stomach it causes loss of appetite, nausea, vomiting, and epigastric pain. In the intestine it produces colicky pains and diarrhœa. By irritating the respiratory tract it gives rise to coryza, cough, hoarseness, huskiness of the voice, oppression of the chest, retro-sternal pain and bronchitis, with occasional hæmoptysis. In the eyes it causes irritation, conjunctivitis, and œdema of the eyelids. In the skin it produces all sorts of eruptions, nettlerash, redness, papules, pustules, vesicles, and boils. Three of the most marked are pigmentation, herpes, and a condition to which the name of "keratosis" has been given, in which the epidermis peels off the palms of the hands and soles of the feet in large flakes. Keratosis is probably due to the local action of arsenic upon the skin, for Ringer and Murrell found that in frogs poisoned by it the cuticle could be readily stripped from the body, and Nunn showed that this is due to softening of the protoplasm in the epidermis, so that it becomes almost completely detached from the dermis. The herpetic eruptions, as well as loss of hair, brittleness or shedding of the nails, excessive sweating and subcutaneous œdema, however, are probably dependent rather upon the action of arsenic on the trophic or nutritive nerves of the skin to which reference will afterwards be made. During its circulation in the blood arsenic acts on the muscles of the limbs, on the muscular fibre of the heart, on the liver and other glandular organs, and especially upon the nerve trunks, although it acts, also to a small extent, on the spinal cord and brain. It thus tends to cause anæmia as well as fatty degeneration of the muscles and of the heart, so that the limbs become feeble and the heart so weak that death may occur from its failure. The liver also undergoes fatty change. The nervous system, and especially the nerve trunks, are especially attacked by the poison. Nerve trunks usually contain fibres having three different functions—namely, sensory, motor, and trophic or nutrient, and all those functions are altered by the inflammation which arsenic produces in the nerve trunks. The alterations are of two kinds; first, the nerves are unable to do the things they ought to do; and, secondly, they do things they ought not to do. The sensory nerves, instead of conveying definite impressions to the brain, become dulled, so that the patient does not feel external objects with the same accuracy that he or she ought, and in consequence complains of numbness and may be unable to distinguish where or what things are, and may thus, for example, be quite unable to sew, or even to write, and may drop things from the hand unwittingly, while the patient may feel as if his feet were walking on wool instead of on the floor. At the same time, the sensory nerves convey to the patient impressions for which there is no real objective ground. He may feel as if pins and needles were running into him or insects were running over him, or he may feel intense burning or pain of all sorts in various parts of the body, and both the skin and the muscles may be so abnormally tender that the slightest touch or pressure is not felt as touch or pressure, but causes the most intense suffering. On account of the weakness of the motor nerves the patient soon gets tired and then certain muscles become so weak as to act only imperfectly, or may become completely paralysed and not act at all. On this account the gait becomes feeble and staggering, the feet drop, the hands drop, the patient becomes unable to walk or to stand, and may be even unable to feed himself, while on account of the diaphragm being weak or paralysed the respiration becomes feeble and imperfect. By stimulating the trophic or nutrient nerves, and perhaps by directly altering the tissue change of the parts themselves, arsenic may at first appear to increase nutrition, so that small quantities render animals or men taking it plumper and more active, their hair grows more thickly and their skin appears clearer than before. But if this point be overpassed the animals or men become thinner and wasted, the skin dry and hard, peeling off in scales and often much pigmented. This pigmentation varies in appearance. It is sometimes slight but general, sometimes patchy, and sometimes so generally diffused and deep in colour as to make the patient appear to belong to a dark-skinned race. The peeling of the skin generally occurs in bran-like scales, but the epidermis may separate from the soles of the feet and palms of the hands in very large flakes. To this the name of "keratosis" is given. Local swellings of an œdematous or dropsical nature may occur in various parts of the body and are particularly noticeable in the eyelids. The spinal cord may also undergo alteration, and some of the neuralgic pains, the loss or perversion of sensations of heat or cold, loss of reflexes and want of coördination in movement, may be partly due to alteration in it as well as to alteration in the nerve trunks. In some cases, although rarely, the brain has been found to be affected and symptoms of melancholia or mania have occurred. The nervous ganglia of the heart may be weakened, and this, along with the feebleness of its muscular fibre, already mentioned as due to arsenic, may lead to syncope or even to death. The nerves which regulate the contraction of blood-vessels are said by Bohm to be paralysed by large doses of arsenic, so that the vessels dilate, especially those of the abdomen, and this, along with the weakness of the heart, explains the low tension of the pulse observed in severe cases during this epidemic. The blood-vessels of the soles of the feet and of the palms of the hands become much dilated, so that the skin of these parts towards the outside becomes very red and at the same time it becomes exquisitely tender and very painful. This condition is known under the name of "erythromelalgia."

---

[1] [illegible] made by Sir [illegible] runton to the Royal Com- [illegible] upon arsenic [illegible] (see p. 1310).

[2] Philosophical Transactions, 1812, Part I, pp. 203, 210.

All the symptoms I have mentioned may occur in chronic arsenical poisoning, but they may not all appear in the same person or to the same extent, for their occurrence may depend upon the quantity of arsenic they have taken, upon the length of time its administration is continued, upon the form in which it is taken, and upon the personal peculiar idiosyncrasy of the person taking it. Small quantities of arsenic, such as one fiftieth to one-tenth of a grain, may be taken by many people for months together with no apparent bad health, but, on the contrary, with better nutrition and increased strength. In these cases it is probable that the whole of the arsenic is eliminated daily as quickly as it is taken, and that there is no storage of it within the body, but if larger quantities are taken, so that the whole is not eliminated, it will gradually accumulate and symptoms of poisoning begin to occur which may become very severe or fatal. Yet if the administration of the drug be stopped before a fatal issue is reached the poison which has already been stored up in the body is gradually excreted and the patient may recover even when apparently at death's door. But during the process of elimination symptoms of sub-acute poisoning may occur and the arsenic which has been stored up for awhile in the body may in passing out through the mucous membranes of the intestine and stomach irritate them and produce vomiting and purging, as in some of Dr. Dixon Mann's cases, three weeks after the arsenic had ceased to be taken.

The effect of arsenic can be modified by the age, strength, and constitution of the patient taking it, women usually being able to take less than men and children very much less than either. Susceptibility to arsenic varies very considerably, and while three minims of Fowler's solution, which is a 1 per cent. solution of arsenic and is the preparation commonly given in medicine, will sometimes cause such symptoms of intestinal irritation as will necessitate its discontinuance, other patients will take 30 minims, or even more, three times a day without any discomfort whatever. The way in which it is given alters its action, so that if five minims of Fowler's solution were given on an empty stomach three times a day it would probably produce irritation of the stomach and intestines, whereas if given when the stomach was full it would be diluted by the food and be absorbed without producing any local irritation whatever. When much diluted in the form of beer the local action of arsenic on the stomach and intestines at the time of taking it is probably very slight and the gastro-intestinal irritation observed during this epidemic was comparatively trivial as compared with the other symptoms and was probably due to irritation of the mucous membrane occurring during its elimination. During the circulation of arsenic in the blood it is not improbable that its action may be determined to one part of the body or to another by other substances taken at the same time. A well-marked instance of this kind of action is known in the case of mercury. Alcohol is well known to have a strong affinity for the nervous structures in the body, whilst that of mercury is much less. But alcohol seems to direct mercury to the nervous system and cause it to act upon them. An example of this is given by the fact that during the preparation of an alcoholic compound of mercury, called mercuric methide, two chemists who were subjected to the fumes were poisoned by the compound and showed signs of nervous disease, one of them becoming maniacal and dying within three months, and the other becoming idiotic and dying after about a year's confinement in a lunatic asylum. Osler has observed that mercury taken along with alcohol seems to have more tendency to produce peripheral neuritis than if taken alone, the alcohol seeming, as it were,—to direct the mercury to the nervous system. If the statements made by some of the patients who have suffered in the present epidemic of this arsenical poisoning as to the quantity of beer they have taken are correct, the amount of arsenic consumed in some cases must have been so exceedingly small as to lead one to ask whether the neuritis can be due to arsenic alone, even though its action may have been directed to the nerves by alcohol or hops, or whether some other poison besides arsenic has not been present in the beer, or whether the arsenic is not present in such a combination as to have a much more deleterious action than that of pure arsenic itself. There are difficulties in accepting the statements of some of the patients as correct, for in the case of Alice Booker, which terminated fatally, and in which Dr. Stevenson separated a weighable quantity of arsenic from the viscera, the patient only admitted having taken less than one pint per diem. It is quite possible that arsenic may be present in beer, combined with either a hydrocarbon or with a proteid, for although it is said not to unite with albumin to form an albuminate it has been found to enter into combination with casein. At present, however, this is only a hypothesis, and Professor Hewitt and I are at present engaged in investigating the subject. It is, however, a research full of difficulties, and if we succeed in obtaining definite results at all it will probably not be until after the expiration of several months at the earliest.

In an epidemic of arsenical poisoning at Würzburg, where the arsenic was contained in bread, only one case of paralysis was observed in 373 cases of poisoning. This extraordinary want of action on the motor nerves when taken in bread as compared with its action when taken along with alcohol in beer or wine tends to substantiate my hypothesis.

I have heard doubts expressed as to whether the epidemic in Manchester was due to arsenic at all, and I confess that when I first went I thought that possibly the symptoms might be caused by organic impurities in beer, such as some of the higher alcohols—e.g., fusel oil, by albumoses, or by furfural. But an examination of the facts has convinced me that the epidemic was due entirely, or almost entirely, to arsenic. No doubt neuritis may be produced by toxins of an *albuminous nature, such as occur in the body in diphtheria*, in plague, and in beri beri, or are found outside the body in diseased grain, such as ergot and maize, producing ergotism and pellagra. But in the present epidemic the cases of illness were distinctly traced to beer. There was no diseased grain used in its production, no evidence of any infective disorder; in fact, there has been no evidence of the presence of anything excepting arsenic, and possibly selenium, that would produce the symptoms. These symptoms, consisting in a combination of gastro-enteric irritation, peripheral neuritis, pigmentation, and eruptions of the skin, are almost characteristic of arsenical poisoning. They occurred in previous epidemics. For instance, in the one which occurred in Hyères, in which a number of persons were poisoned by arsenic in wine, the symptoms were almost identical with those of the present epidemic. In both these epidemics the symptoms may be conveniently classed in the manner adopted by MM. Midal and Ollivier for those observed at Hyères into—(1) digestive, (2) cutaneous, and (3) nervous. In both epidemics the digestive symptoms were not nearly so prominent as would have been expected from the well-known irritant action on the digestive canal which arsenic produces in cases of acute poisoning, and in some cases symptoms of this sort were completely absent. They seem to have been rather more marked at Hyères than at Manchester, a circumstance which one would naturally expect both from the more irritating action of wine as compared with beer on the mucous membrane of the stomach and intestine, and from the larger proportion of arsenic in the wine (0 08 gramme per litre). The digestive symptoms were alike in both epidemics—viz., loss of appetite, vomiting, abdominal pain, and diarrhœa. Retro-sternal constriction or pain was noted in both, and I have mentioned it already along with cough, but at Hyères it was attributed to digestive derangement. In both epidemics the symptoms produced during absorption were slight in comparison with those which occurred during the circulation of the poison in the system and during its elimination. The cutaneous symptoms which occurred were of the most varied kind in both epidemics. In Hyères the forms were so manifold as to exhaust dermatological nomenclature, and they were no less so in Manchester. In both epidemics two of the most striking cutaneous symptoms were pigmentation of the surface generally and separation of the epidermis from the feet and hands in such huge flakes that it seemed as if the whole skin of the soles and palms came off in one piece (keratosis). At Hyères coppery patches on the skin and an eruption the colour of burnt coffee were noticed, but the pigmentation does not appear to have been so dark or so extensive as in some of the cases at Manchester. In both epidemics the nervous symptoms were the most important, and in both cases they were at first attributed to alcohol and not to arsenic. In both epidemics, although numbness and loss of sensation were observed, they were not such prominent symptoms as pain and tenderness, weakness and paralysis. In both pain was a most marked feature, varying in intensity from slight "pins and needles" to most intense agony; and a very striking symptom was extreme tenderness to touch or pressure, so that the patients could not bear the pressure of the bedclothes on their limbs. Extreme tenderness of the calves and other muscles of the body on pinching, as well as the redness and exceeding painfulness of the soles of the feet and palms of the hands (erythromelalgia), which were so marked in the Manchester cases, are less prominently noticed in the accounts of the Hyères epidemic. Something of the same kind seems, however, to have been present, for the patients are said to have complained of pain as if dogs were gnawing their calves and the soles of their feet. In both epidemics the muscular weakness or paralysis, the difficulty in walking, the peculiar gait, and sometimes the complete inability to stand, were all alike. Both resembled each other, also, in the affections of the respiratory system; indeed, with the slight difference indicated already, the symptoms in one epidemic might stand for those of the other. In both epidemics there can be little or no doubt that the symptoms were chiefly, if not entirely, due to arsenical poisoning, for (1) there was an absence of any other sufficient cause; (2) there was sufficient arsenic to cause symptoms of poisoning; and (3) the symptoms corresponded with those which have been observed in cases of chronic poisoning by arsenic taken in other ways.

When I first went to Manchester to investigate the *epidemic I started with the idea that the symptoms of* poisoning were probably due, not to the arsenic in beer, but to some other impurity, but I soon found that the arsenical origin of the epidemic could be proved beyond a doubt. The present epidemic is certainly due to contamination of beer through glucose and invert sugar made by one particular firm, who had been supplied with sulphuric acid containing a very large quantity of arsenic. The extraordinary number of cases of peripheral neuritis which have occurred in this epidemic, together with the fact that this disease has been specially observed and described by two Manchester men, the late Professor Ross and Professor J. Dreschfeld, naturally raises the question whether the peripheral neuritis, a disease which is commonly attributed to alcohol, is not caused in most, if not in all, cases by arsenical poisoning and whether poisoning by arsenic may not have been going on to a greater or less extent in Manchester for many years. A good deal may be said on both sides of this question. On the one hand, it cannot be denied that peripheral neuritis may be caused by toxins, for it is found in diphtheria where no poison except that of diphtheria has gained access to the organism, and Sidney Martin has shown that the diphtheritic toxin, apart from the bacillus, will produce neuritis in animals. But, on the other hand, although it is commonly supposed that alcohol will cause the disease, it is by no means certain that ethylic alcohol will do so, and alcoholic neuritis in spirit-drinkers may possibly be due to other substances than ethylic alcohol. A remarkable observation was made to me in a letter by Sir William Gairdner. About 16 years ago he was examining in Manchester and went through the wards of the late Dr. Ross. He saw there several cases of peripheral neuritis and was much astonished because he could not recollect seeing more than two cases in Glasgow in all his life. He wondered if he could have overlooked the disease, but after consideration he came to the conclusion that it did not exist in Glasgow, notwithstanding the large quantity of whisky which was drunk there and ought to have produced the disease if it were due to alcohol as usually supposed. The fact that arsenic has now been found both in hops and malt renders it not improbable that cases of peripheral neuritis in Manchester may for years past have been due to a certain amount of contamination of beer by arsenic through hops and malt, and although it is not yet certain it seems probable that this contamination may have arisen from the use of coal or coke containing arsenic in the process of drying.

The recent and remarkable discovery of selenium in beer by Dr. Tunnicliffe imports a new factor into the question, but further information is required before any conclusion can be arrived at as to whether this substance may be partly to blame for producing neuritis, and if so to what extent.

The occurrence of this epidemic has caused an outcry against the practice of using glucose and invert sugar in brewing and a demand that only barley and hops shall be employed. But I am informed that this would render it difficult to brew the light beers similar to the German lager or Pilsener beers which have come to be so extensively drunk in this country within the last 30 years. I regard the introduction of such light beers as a benefit to the public, for it supplies a drink which can, if pure, be taken without causing the heaviness, drowsiness, stupidity, and headache which so commonly follow the consumption of heavy ales.

Although this epidemic has done much harm, has caused great pecuniary loss to the brewers, who were not to blame, and, still worse, has caused great pain, paralysis, and, in some cases, death, to the unwitting consumers of the contaminated beer, it has not been without its advantages For it has shown how a poisonous substance may find its way into a chemical, and through it, not only into beer, but many other substances used as food. It has shown, also, how a poison like arsenic may find its way into food in such unexpected ways as through hops and malt and thus enforces the necessity of guarding the consumer, not by placing restrictions upon manufacture, but by demanding that the manufacturer shall in the future be held responsible for the purity of the articles he sells, and that all materials for beer or foodstuffs should be sold with a guarantee of purity which should be rigorously enforced.

Stratford-place, W.

SOME FURTHER INVESTIGATIONS UPON RHEUMATIC FEVER.

By F. J. POYNTON, M.D., M.R C P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;

AND

ALEXANDER PAINE, M.D. LOND.,
ASSISTANT BACTERIOLOGIST TO ST. MARY'S HOSPITAL.

SINCE our first contribution to this subject, published in THE LANCET of Sept. 22nd (p. 861) and 29th (p. 932), 1900, we have continued our investigations and have now isolated the diplococcus from 16 cases of rheumatic fever. The particular point upon which we are still intent is to establish this diplococcus as a cause of rheumatic fever. If this can be firmly established then the many difficulties that must subsequently be faced can be dealt with from a firm basis. In no disease perhaps more than in rheumatic fever is it necessary to make this ground sure, for it is in the centre as it were of a group of diseases, which not only may resemble rheumatic fever closely in their clinical features, but which are also the result of infections in all probability closely allied to the infection of rheumatic fever. The differential study of the streptococcal, staphylococcal, pneumococcal, gonococcal, scarlatinal, rheumatic, and probably rheumatoid infections is one of great difficulty. The morphological characters of the various organisms can only offer a partial assistance and chemical pathology has not yet advanced sufficiently to render much service, though the important investigations of Dr. Sidney Martin upon diphtheria and ulcerative endocarditis and the numerous researches both in this country and on the continent into the nature of the toxic processes due to microbic infections are indications of the increasing importance of this subject. It is for these reasons that we have entered into such detail in our efforts to prove that this diplococcus is a cause of rheumatic fever, and it is upon this detail that we especially rely.

I.—THE ISOLATION OF THE DIPLOCOCCUS FROM THE NODULE.

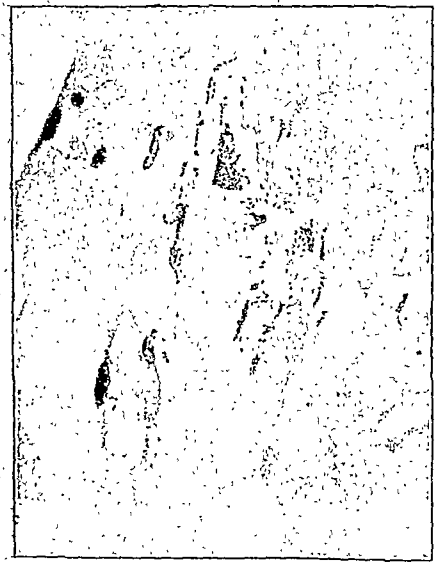
The first series of additional facts that we are able to bring forward in this paper is concerned with the rheumatic nodule. We have succeeded in demonstrating the organisms in two more nodules and have in addition grown them in the nodular tissue outside the body in pure culture. We have produced in a rabbit, as the result of an intravenous inoculation from this culture undertaken for us by Mr. H. G. Plimmer, pathologist to St. Mary's Hospital, a condition we believe to be that of acute rheumatism—namely, polyarthritis, pericarditis, and multiple valvulitis, all non-suppurative. Finally, we have isolated the organisms in pure culture from the joints of the animal after death and thus completed the chain of proof. And since these formations are looked upon by general consent as highly characteristic of rheumatic fever the isolation of this diplococcus from one of them will appeal to many as a strong link in the proof of the causal relation of these organisms. A short outline of the investigation and the sketches subjoined will give a clearer idea of the value of this evidence. We are indebted to Dr. W. B. Cheadle for permission to make use of the clinical notes of the case and to Mr. H. G. Plimmer for the details of the necropsy.

A child, aged nine years, was admitted to St. Mary's Hospital on Nov. 3rd, 1900, suffering from acute rheumatism. When four years old she had suffered from chorea and since then from three attacks of acute rheumatism. The present illness had commenced four weeks before admission with arthritis and for three weeks there had been shortness of breath. The patient was pale and thin, the pulse-rate was 100, the temperature was 102·4° F., and the respirations were 40. There was dyspnœa and there was also advanced heart disease. Both the mitral and aortic valves were affected and the heart was dilated, but there was no sign of pericarditis. The knees and right elbow-joint were painful but there was no effusion. Over both elbows and over the knuckles there were numerous small nodules. The urine contained a trace of albumin. At first the child seemed to improve, though it was noted that the nodules were increasing in size. On Nov. 7th acute œdema of the lungs developed and proved rapidly fatal.

The necropsy showed recent transparent, bead-like vegetations upon the mitral, tricuspid, and aortic valves, and the mitral and aortic valves were also thickened from the results of previous inflammation. There was no pericarditis but there were 25 cubic centimetres of a straw-coloured fluid in the pericardium. The lungs were œdematous and in some places there were hæmorrhages into the alveoli and in others collapse. The liver was "nutmegged," the spleen was small and firm, and both kidneys showed cloudy swelling of the parenchyma of the convoluted tubules. Two hours after death we removed three nodules from the right elbow with strict aseptic precautions. One of these we at once placed in the medium of milk and bouillon rendered slightly acid with lactic acid. The second we cut with a sterile knife, then scraped, and with the scraping inoculated a second tube. The third we "fixed" at once in perchloride of mercury. Both tubes were incubated anaerobically. The tube inoculated with the exudation remained sterile. The tube containing the entire nodule showed no growth upon the first day, but upon the third day a pure culture of the diplococci. The organisms were transferred to blood-agar tubes and grew in the usual small, white, discrete colonies The contents of five of these tubes were injected intravenously into a rabbit on Nov. 11th The result of the intravenous inoculation was as follows. The next day the heart was very rapid and there was a definite systolic mitral murmur, and upon the second day the hind limbs were stiff. The murmur then disappeared, but a week after inoculation the left fore and hind limbs were almost powerless, and in the next few days this weakness and stiffness spread to all four limbs. A fortnight after inoculation a systolic murmur had reappeared and there was definite pericarditis, but the stiffness had disappeared and the joints were none of them swollen. We were anxious to obtain a definite arthritis with effusion, because we have found that these effusions afford the easiest and most reliable local lesions from which to cultivate the organism. Accordingly, on Nov. 26th—that is, the day after we had noticed that the stiffness had disappeared—the animal was again inoculated with the organism which had been kept growing in the acid milk medium. Two days afterwards stiffness of the limbs appeared, then the right shoulder swelled, and five days afterwards both knee joints. The animal was killed next day and the post mortem examination showed mitral and tricuspid valvulitis, pericarditis of some standing, and an opaque fluid in the right knee-joint. There was no suppuration in the viscera. Cultivations were taken from the joint and a pure growth of the diplococcus obtained. The nodule which had been incubated was by this time in a pulpy condition from the effects of the liquid medium in which it had been lying. This we fixed and hardened in alcohol and finally embedded and cut in paraffin. The accompanying illustration (Fig. 1) shows the prolific growth of the diplococci. The nodule that we fixed in perchloride of mercury was also hardened and cut, and in the outer zone we found some groups of the diplococci (Fig. 2). It will be seen from this account that every circumstance was favourable for the success of this investigation and the proof a very conclusive one. In our previous papers we also recorded that intravenous inoculations of the diplococcus had produced in one instance a nodule over a vertebral spinous process and nodular formations around the joints which microscopically resembled the structure of an early nodule in man. Also that subcutaneous injection of a virulent culture had produced a large swelling which, slightly tender at first, had gradually disappeared without any evidence of suppuration.

This method of incubating the nodule may possibly be of some service to others who are interested in this subject. We believe that in the local lesions of rheumatic fever the struggle between the organisms and the tissues is so evenly balanced that in many instances at the time of death the diplococci are many of them destroyed. If, then, with due precaution, a lesion in the so-called "active" stage be removed and incubated in a suitable medium the organisms should grow, for there is now no resistance to prevent their growth. *It is very possible that they do not regain their full* vitality, but they can be easily demonstrated and may, as we have shown, produce experimental results. Recently we have adopted this method for the cardiac valves and instead of curetting them have snipped off the granulations, incubated them in the acid medium, and in this way obtained a pure growth of diplococci.

FIG. 1.



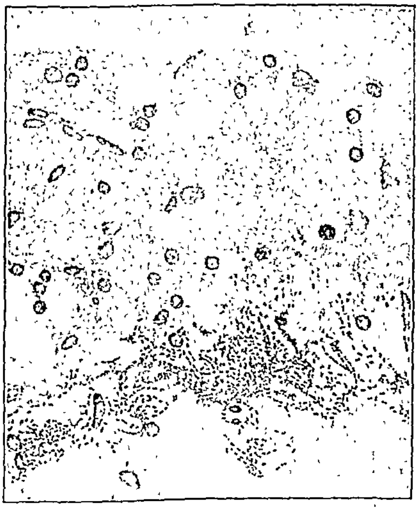
A section through the outer zone of a recent rheumatic nodule, showing groups of the diplococci lying in the interstices of the swollen connective tissue. The nodule was removed with strict aseptic precautions two hours after death and at once placed in a saturated solution of perchloride of mercury.

Summary.—To sum up, (1) we have demonstrated the diplococcus in three rheumatic nodules taken from two cases of rheumatic fever; (2) we have isolated the diplococcus from the nodule in one instance in pure culture; (3) intravenous inoculation of this culture has produced valvulitis, pericarditis, and polyarthritis in a rabbit; (4) we have isolated the diplococcus from the joint exudate of this rabbit; and (5) the nodule is looked upon as a highly characteristic manifestation of rheumatic fever, therefore we conclude that this investigation lends strong support to the contention that this diplococcus is a cause of rheumatic fever.

II.—OBSERVATIONS UPON THE PATHOLOGY OF RHEUMATIC CHOREA.

In our paper upon the Pathogenesis of Rheumatic Fever, read before the Pathological Society of London in October, 1900, we recorded a condition produced by the intravenous inoculation of the diplococci into a rabbit which we believed to be chorea. This rabbit was extremely nervous, and in addition manifested sudden twitching movements of the limbs and face. These movements were definite, but not violent, and there was about them that peculiar, sudden, involuntary character, which is so characteristic of slight rheumatic chorea. At the time of the reading of this paper we had not examined the brain further than to be able to state that there was no visible meningitis. Since then we have investigated much of it and have found diplococci in the pia mater and in the endothelial cells of the blood capillaries, dipping into the motor cortex from the surface (Figs. 3 and 4). The pia mater in places showed some slight swelling of its connective tissue and cell exudation. The organisms were also present in the walls of some of the blood-vessels of the pia mater. The rabbit, which suffered from chorea and also valvulitis and polyarthritis, was the only one in a series of inoculations from animal to animal that showed these movements. The others (rabbits No 1, 2, 3, 4, and 5 in the original paper in THE LANCET) showed numerous manifestations of rheumatic fever but not any movements of this nature. The fatal case of rheumatism from which the culture was obtained was recorded (Case 4) in THE LANCET and the growth was obtained in the pericardial fluid itself after incubation. On another occasion we isolated the diplococci from the cerebrospinal fluid of a rabbit suffering from valvulitis and pericarditis, but the animal had shown no signs of chorea. Again, we noted in a third rabbit weakness of the hind limbs, which we suggested might be paralytic chorea. In a case of fatal chorea we discovered micrococci in the mitral valve and in the motor cortex, but the organisms were never isolated, and this observation at the best is not more than suggestive. Finally, on three occasions we have isolated the organisms from the blood in acute rheumatic pericarditis. This is a proof that they circulate in the blood stream, and therefore presumably circulate in the cerebral vessels and possibly escape to the cerebral tissues in acute rheumatism with pericarditis.

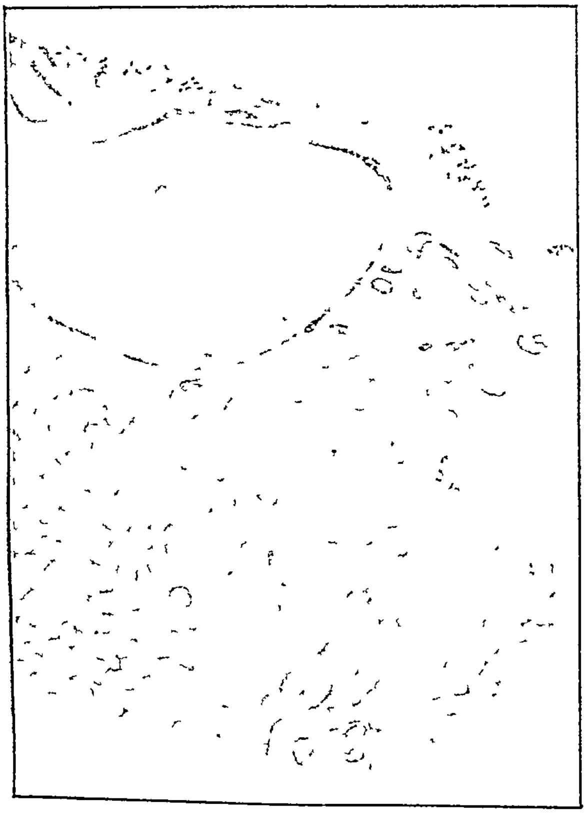
FIG. 2.



Section through a rheumatic nodule removed two hours after death with strict precautions and incubated anaerobically in the milk, bouillon, and lactic medium. The tissues are altered in appearance from soaking in the medium previously to fixation, but the free growth of the diplococci is clearly seen at the lower margin of the figure.

The conclusion to which these observations appear to lead is this—that the commencement of rheumatic chorea is associated with the presence of the diplococci in the brain and perhaps pia mater, as well as with the presence of toxins produced by these organisms. If this be so, then we should be prepared to find that, with due allowance for the special anatomical characteristics of the brain, the morbid changes produced would be analogous to those presented by the other local manifestations of rheumatic fever. We can speak with confidence of the nature of these changes in the cardiac valves, myocardium, pericardium, and nodules. The connective tissues swell, there is hyaline degeneration, and there may be necrosis. The connective tissue cells proliferate. Where there are blood-vessels there is hyperæmia and there may even be small hæmorrhages; there is also fibrino-cellular exudation. The cardiac muscle fibres then lose their striation and there may be well-marked fatty changes. If the process has been less severe but of long duration there is sclerosis spreading, especially from the position of the small blood-vessels. Then we also know that the diplococci in the valves, pericardium, and nodules are rapidly destroyed at the sites of the lesions, though it is probable that the poisons that are produced may linger after the disappearance of the organisms. But we are in ignorance as to the nature of any poisons that may be formed by the action of the diplococci.

FIG. 3.



A section through the pia mater and adjacent brain tissue of a rabbit that suffered from polyarthritis. Mitral valvulitis and choreiform movements, the result of intravenous inoculation with the diplococcus. Numerous diplococci are seen in the pia mater close to a large capillary, the lumen of which is only partially visible in the figure. The connective tissue of the pia mater is slightly swollen.

If these observations are applied to the pathology of rheumatic chorea we should expect to find that the lesions are various. In very acute and rapidly fatal cases we should expect hyperæmia, possibly small hæmorrhages, and foci of necrosis in the cerebral tissues; also minute emboli or thromboses in the terminal capillaries. In the less acute cases we should expect changes in the region of the minute blood capillaries, such as cell-exudation and cell-proliferation and also degeneration of nerve-cells. In the chronic cases we should expect perivascular fibrosis and small areas of sclerosis. There would probably be considerable difficulty in demonstrating the organisms, especially in the more chronic cases; on the other hand, it is quite possible in some cases that they may be present in sufficient numbers to block the most minute of the blood capillaries, or escaping from the vessels into the brain tissue to set up such swelling in the neighbourhood of these minute capillaries as to cause their occlusion from pressure upon the delicate walls. Our investigations throw no light upon the regional localisation of chorea, neither do they throw light upon the action of toxins or the characteristics of the brain itself, both most important factors in the pathology of chorea. It would, however, appear probable that the actual commencement of chorea in rheumatism is usually associated with the presence of the diplococci in the brain.

Up to this point we have contented ourselves with reasoning from our facts upon the pathology of chorea. It now remains for us to allude to some of the numerous observations of other investigators upon this subject which have, it is clear, guided us in arriving at these conclusions and which are of the utmost importance in any investigation of such a nature as this one In 1863 Dr. Kirkes,[1] noticing the constant presence of vegetations on the valves of the heart in fatal chorea, suggested that the disease might be caused by the irritation produced in the nerve centres by fine molecular particles of fibrin which were set free from the inflamed endocardium and carried by the blood current into the capillaries of those cavities. Dr. Hughlings Jackson[2] in 1864 wrote: "I think from many circumstances that embolism is a frequent cause of chorea. I do not say plugging of the trunk of the middle cerebral, but probably of some of its ramuscules which supply convolutions near to the corpus striatum." In 1865 Sir William Broadbent,[3] by an independent research, arrived at much the same conclusion as had Dr. Hughlings Jackson, and also laid stress upon the importance ot alterations in the blood as a predisposing cause. Dr. H. M. Tuckwell[4] in 1867 published a case of chorea in which the necropsy disclosed an extensive superficial softening of the convolutions the result of embolism. And again in the St. Bartholomew's Hospital Reports for 1869 he recorded another fatal case in which there was embolism of the right posterior cerebral artery and figured in a plate both the mitral valve and the vessel that had been plugged. It is impossible to over-estimate the value of those researches, for they at once brought

the subject into the field of controversy and put forward an hypothesis capable of proof or disproof.

The whole question of cerebral disease was further advanced by the experimental researches of Fitz, Hitzig, Ferrier, and others upon cerebral localisation. Later opponents arose to the embolic theory, Ogle, Barnes, Dickinson, Bristowe, and Bastian in particular advancing objections to this hypothesis. Dr. Dickinson,[5] in 1876, wrote thus upon this question: "We see in chorea a widely distributed hyperæmia of the nervous centres, not due to any mechanical mischance, but produced by causes mainly of two kinds—one a morbid, probably humoral, influence which may affect the nervous centres as it affects other organs and tissues; the other, irritation in some mode, usually mental, but sometimes what is called reflex, which especially belongs to, and disturbs, the nervous system and affects persons differently according to the inherent mobility of their nature. The course of the disease is sufficiently traced in hyperæmia and its results." Dr. H. C. Bastian[6] in 1877, in a paper entitled "Remarks on the Pathology of Chorea," writes: "In common with many who have spoken with greatest authority on this subject I look (certain rare cases excepted) to an altered and often anæmic blood-state as its predisposing cause in individuals of a certain age and nervous temperament. Secondly, I look to the irritation in such individuals of a disturbed nutrition in the corpora striata and adjacent parts of the brain, tending to issue and often actually issuing, in what for want of any more appropriate term may be called a subacute inflammation of these centres—often characterised in part by the production of multiple minute thromboses." In 1876 Dr. Hughlings Jackson, after alluding to those cases of chorea in which Dr. Bastian found plugging due to thrombosis, writes: "It may be, I would admit here, that the hypothesis of embolism will be displaced by Bastian's hypothesis of thrombosis as an explanation of many cases of chorea." In a footnote to this paper he further writes: "Having regard to the great elaborateness of the movements in chorea I still think it most probable that the convolutions are the parts diseased." Since the time of those papers numerous investigators in England and on the continent have proved beyond controversy that chorea and rheumatic fever are very frequently associated, so frequently, indeed, that some have thought that all chorea was the result in some way or other of rheumatism. As this association became more certain it was natural that the view that some poison the result of the rheumatic state was the actual cause of chorea should gain many adherents. A considerable amount of information has also been gained about the morbid anatomy of fatal chorea, though, as pointed out by Dr. Risien Russell[7] in his article upon Chorea in Professor Clifford Allbutt's "System," many of these investigations have not been sufficiently thorough. It is easy to understand the difficulty of such investigations when it is borne in mind that those who have undertaken them have had but little to guide them as to what to look for or where in such a large organ as the brain to look. It would appear, nevertheless, that the more careful the researches the more frequently have some definite morbid changes been discovered.[8] Hyperæmia appears to be common, as also softening from the effects of minute emboli.[9] Punctiform hæmorrhage and perivascular exudations have also been found.[10] The late Dr. Charlewood Turner[11] described cloudy swelling of the large pyramidal cells, and Dana[12] hyaline swelling of nerve cells and chronic lepto-meningitis.

Another result of the establishment of the association of rheumatic fever and chorea was the view that the changes in the brain were analogous to those which occur in the valves of the heart and in the subcutaneous nodules. To quote from the Harveian Lectures for 1888, by Dr. W. B. Cheadle,[13] "I may point to the possibility of some proliferative change in the neuroglia akin to that of the fibrous tissues elsewhere as a point which needs examination." If these local lesions in rheumatic fever be each one of them looked upon as an individual and complete rheumatic process, then we have the clinical expression of such a view as the above in the statement by Sir Dyce Duckworth[14] that chorea is cerebral rheumatism, in support of which in 1894 he read a paper at Rome at the International Congress of Medicine. Again, in a recent communication to us Dr. Hughlings Jackson refers to the possibility that some of the changes in the brain are analogous to those found in the cardiac valves and subcutaneous nodules. On the other hand, the view that chorea was in most part the direct effect of rheumatic fever was opposed by such an authority as Sir William Gowers[15] in his "Manual of Diseases of the Nervous System" in 1893. He admitted the frequency of association of the two, but writes: "The hypothesis which seems best to explain the facts is the old theory that the common cause of the endocarditis and the chorea is a blood state allied to, but not identical with, that which causes acute rheumatism." He considered that the facts suggested a toxic change of a chemical character rather than an organised virus.

One of the most recent researches upon the morbid anatomy of acute chorea is that of Dr. Bertram Abrahams.[16] The patient, aged 28 years, was pregnant; there was a history of scarlet fever but not of rheumatic fever and during life there was a systolic mitral murmur pointing to slight mitral endocarditis. The illness lasted from April 25th, 1899, to June 1st. The motor cortex showed changes, especially up the right side in the region of the right parietal lobe. In this region there was a profuse exudation of small cells which were found to be uninuclear leucocytes. In some sections these cells could be traced passing through the walls of the small blood-vessels and outside the vessels occupied the peri-neuronal lymph spaces. There were haziness and swelling of the pyramidal cells. There was no trace of micro-organisms. Dr. Abrahams in his comment writes as follows: "I would venture, however, to submit that it tends to support the following general deductions. Firstly, the changes noted are sufficient to explain the clinical manifestations of the disease on the ground of disturbances in the cells of the so-called motor cortex. Secondly, their nature is such as to be susceptible of complete and rapid recovery—a fact in harmony with the description of the disease as functional. Thirdly, there is nothing in them inconsistent with the conception of chorea as an affection produced by a blood state—namely, the rheumatic toxæmia." With the development of bacteriology new facts were obtained, and during the last 15 years the opinion that rheumatic fever was of microbic origin has steadily gained ground. This resulted in the recognition of the possibility that some bacterial poison might be the cause of rheumatic chorea, an idea strengthened by the analogy of the occurrence of diphtheritic paralysis as the result of the infection with the specific bacillus of diphtheria. But though the view that the condition might be the result of some poison circulating in the blood gained in force, there still, we believe, must be recognised the clinical fact that rheumatic chorea is often remarkably asymmetrical in its distribution, sometimes focal, and this, we think, militates against the theory of a diffuse poison being the only casual agent and points rather to multiple local lesions being present in addition to the more diffuse cerebral toxæmia.

Finally, within the last 10 years various observers have isolated organisms from the brain and its pia mater in fatal chorea. The organisms most usually found have been cocci,[17] though Pianese[18] in 1893 isolated a bacillus which produced convulsions in animals. In 1894 Dana[19] isolated a diplococcus from the meninges, and in 1898 Apert[20] isolated a diplococcus from the brain and was of opinion that the organism was similar to that described by Triboulet[21] as a cause of aggravated rheumatic fever. In 1899 Wassermann and Malkoff[22] isolated from the brain in a fatal case of chorea a diplococcus which produced fever and multiple arthritis in a series of 80 rabbits. This diplococcus Professor Wassermann considered to be the specific cause of rheumatic fever. In 1899 Maragliano[23] as a result of his researches considered chorea to be a cerebral infection by staphylococci, and maintained that the disease was due either to the presence of these organisms or to the poisons which they produced. In 1900 we produced chorea in a rabbit by the intravenous inoculation of a diplococcus which we believe to be a cause of rheumatic fever, and demonstrated the organisms in the pia mater and in the endothelial cells of the blood capillaries dipping in the cortex.[24]

It remains for us to consider some of the clinical characteristics of rheumatic chorea and to attempt to explain them by the hypothesis that in most cases, possibly all, the commencement of the disease is the result of the actual presence of the diplococci together with the poisons they produce in the brain. Any such considerations must be limited by our ignorance of the part taken in the disease by the brain itself, which fact is without doubt a very important one, and also by our ignorance of the exact action of the toxins that are produced by the organisms. Further, our observations do not throw any definite light upon the localisation of the lesions. The hypothesis involves the consideration of two morbid processes in the actual production of the disease—one, focal, dependent upon the tissue-changes in the regions where the diplococci are located, the other dependent upon the toxic effects of the poisons upon the nerve elements. How much is to be attributed to each factor will be made far more clear when these poisons can be isolated and studied by experiment.

The onset of chorea is usually gradual, sometimes acute, in rare cases almost sudden. In the acute it is reasonable to suppose that there is invasion of the brain by diplococci. It is possible that they escape from the vessels and set up swelling and exudation in the surrounding tissues, just as in the nodule they may quite rapidly give rise to a swelling which is perceptible to the eye. In cases of more gradual onset the invasion is probably less severe either in the intensity of virulence or in the number of the organisms that gain access to the brain. The symptoms are sometimes focal and sometimes general, because there are the two processes dependent upon the factors mentioned above. The lesions that are produced usually resemble those represented by the nodules in the completeness of their recovery and also in the varying duration of this recovery. The analogy cannot, however, be pushed too far. We recognise that there is this peculiarity about the cerebral processes, that they are of such complexity that when disordered they are especially slow to return to normal, although the actual cause of the disturbance may have been removed. Some rare cases are fatal, the intensity of the disease resembling then the severe types of rheumatic pericarditis. Other cases recover only partially and for years a chronic condition of disordered movement persists. We should suspect that this points to some actual, though slight, multiple organic lesion, and in such cases, also, some peculiarity in the brain itself is highly probable This view is supported by the pathological changes that have been found in that chronic progressive form of chorea known as Huntingdon's chorea. It was clearly demonstrated by the earliest investigators that the paralytic manifestations mean a more severe nerve lesion than the incoördinate movements. These paralytic symptoms we would associate with acute local tissue changes in the regions invaded by the diplococci.

That only certain cases should develop chorea is remarkable and cannot as yet be explained, but it is only a further evidence of the remarkably specific action of the more complex poisons, the truth of which we have been led to recognise by the study of peripheral neuritis. There is little doubt, too, that in children more cases than are perhaps generally recognised present slight manifestations of chorea during acute rheumatism (a point which has been emphasised by Sir Thomas Barlow), and still more cases without presenting evidence of actual chorea, are highly nervous and excitable during an attack of rheumatic fever. That the disease should be common in children and rare in adults is in accord with what is found with many other acute infections; the child is less resistant to them than the adult, and the manifestations are more widespread.

The causal relation of fright to chorea is, and always has been, a great difficulty. Some authorities—for example, the late Dr. Sturges[25]—have attributed to fright and mental strain a most important position, others with equal ability have opposed this view. The truth probably lies in the middle course. Many of the examples attributed to fright have, no doubt, only proved that the condition of the brain must have been very unstable, and the essential point has been, not the trivial cause of fright, but this condition of instability. It is well known that rheumatic children are often highly nervous and excitable, and especially so before an attack of chorea; this fact has been insisted upon by, among others, Dr. Goodhart, Dr. Cheadle, and Sir Dyce Duckworth, and quite recently by Dr. Still. How much of this instability in any case of chorea is to be attributed to hereditary weakness and how much to latent rheumatic processes it is difficult to decide. At present the pathological processes that result from fright are unknown, though on the clinical side it is recognised that their effects may be as far-reaching and of as long duration as morbid conditions produced by bacterial poisons. The association of fright and rheumatic chorea appears to stand at present thus. Rheumatism produces a cerebral state analogous to that produced by fright; what that condition is we do not know. When chorea arises in a rheumatic child and is attributed to fright it would seem probable that fright acts upon the rheumatic brain much as strain acts upon the rheumatic heart—namely, intensifies the rheumatic process in the brain and precipitates chorea, as does strain hasten the onset of rheumatic carditis. Such a brain previously to the fright is unstable from rheumatic infection and then the fright itself, lowering still more the cerebral resistance, starts sometimes at once, sometimes after a short interval, the actual phenomena of chorea.

III.—THE OCCURRENCE OF THE DIPLOCOCCI IN THE POLYMORPHONUCLEAR LEUCOCYTES.

By centrifugalising the pericardial exudate from a case of acute rheumatic pericarditis we have succeeded in demonstrating the presence of these organisms in the polymorphonuclear leucocytes. In one instance there were as many as three pairs of diplococci in one leucocyte. In rabbits we have also demonstrated them in the same cells in the joint exudate. The fact that the diplococcus can be discovered in the polymorphonuclear leucocytes is of interest because it is well known that there is a moderate leucocytosis in rheumatic fever. It is therefore possible that this leucocytosis is protective in function.

IV.—THE INCUBATION PERIOD OF RHEUMATIC FEVER.

It does not seem very probable from our observations that rheumatic fever has a definite incubation period. If it should so happen that a very considerable infection suddenly occurred, then the symptoms show themselves rapidly. Dr. A. E. Garrod in his treatise gives several examples in which the local symptoms showed themselves on the second day or within the first week, and in these instances there was a very definite history of chill and cold. Rabbits intravenously inoculated usually show the first local lesions at the end of the second or the beginning of the third day. On the other hand, the resistance to the disease being great, it may well be in other instances that for some considerable time the infection is kept at bay and general indeterminate symptoms alone be manifested. Then one of two events may occur: either the resistance may prove effectual and the illness come to an end without having ever been recognised as rheumatic fever, or the infection may conquer and rheumatic fever result after a considerable period of previous ill-health. This occurrence of rheumatic fever after some weeks of previous malaise is thoroughly recognised by clinicians.

In the consideration of this question a study of the tonsils after death is of some interest. These are not uncommonly enlarged and very unhealthy at the time of death, and when sections are made through them scattered foci of inflammatory exudation may be discovered at some distance from the surface (a point insisted upon by Dr. William Hillier), the structure of the tonsil itself is indurated and points to a condition of subacute inflammation and disease of long standing. In such a condition as this we naturally wonder how great possibilities for harm exist in these scattered foci of active disease, to what extent the organisms may develop at these sites, and to what extent they may gain access to the system. The importance of this question has been still more accentuated by the extensive researches of Fritz Meyer, conducted in the laboratory of Professor von Leyden, and published in February, 1901. Meyer, after an investigation extending over two years, succeeded in repeatedly isolating from the throat in rheumatic patients a diplococcus easily decolourised by Gram's method. This grew well on blood agar in staphylococcal masses, and in liquid media of high alkalescence in streptococcal chains, and produced in rabbits the same phenomena as did the diplococcus isolated by ourselves.

[24] Transactions of the Pathological Society, October, 1900.

[25] THE LANCET, Sept. 29th, 1888, p. 605.

V.—IS FEVER A PRIMARY PHENOMENON IN RHEUMATIC FEVER OR IS IT SECONDARY TO THE LOCAL LESIONS ONLY?

Upon this point we are able to bring forward some facts which suggest that fever may be a primary phenomenon of the disease. This view has been held by such authorities as Graves, Todd, Fuller, and others, while, on the other hand, Besnier and Homolle considered the fever to be secondary to the local lesions. In the valuable monograph by Dr. A E Garrod upon rheumatism the evidence for and against these views and the difficulty there is in arriving at a solution of this question are stated with great clearness. As Dr. Garrod has written, "It is only from the presence of the local manifestations that it is possible to be sure of the nature of the attack." Experiment overcomes this difficulty in some measure, but not at present altogether, for we do not understand exactly the method of infection in rheumatic fever. Granting, for example, that the throat is an important site of infection, we cannot say precisely under what conditions the diplococci gain access to the system, though it is probable that the path is through the lymph channels.

The experimental method of intravenous inoculation, on the other hand, is a gross method, for one considerable dose of the organisms is at once injected into the circulatory system and all resistance at the site of inoculation put out of court. Admitting this, it is clear that we can by this means state precisely when infection took place, and therefore can judge whether fever is a primary phenomenon or not under those conditions. We have found the temperature rise within 24 hours, whereas the local lesions usually do not appear until the third day. In one case pericardial fluid from a case of rheumatic pericarditis was removed in sterilised pipettes four hours after death, and then incubated for 24 hours. The fluid contained the diplococci in great numbers. This was intravenously inoculated and four hours afterwards the temperature had risen to 105°. This was a more pronounced rise of temperature than occurred when cultures upon blood agar were used. This result suggests that toxins in the pericardial fluid might have assisted in causing this rapid rise of temperature.

VI.—THE EXPERIMENTAL PRODUCTION OF MORBUS CORDIS.

Whatever views may be held by others regarding the relation of this organism to rheumatic fever there can be no possible doubt that they are capable of producing cardiac lesions with great constancy. We have repeatedly observed the occurrence. The mitral, tricuspid, and aortic valves have all been affected, and, in addition, dilatation of the heart with fatty change in the myocardium and pericarditis have resulted. These results are extremely suggestive of the true meaning of the infection. It seems highly probable, too, that the study of heart disease may be simplified and be made more certain by observations upon the conditions experimentally produced. There is one aspect of this subject which has a very important bearing upon the study of rheumatism, and that is the involvement of the right side of the heart. It is repeatedly stated that the right side of the heart is but rarely affected in rheumatic fever, and so frequently is this statement made that we believe it may lead to error. Sir Thomas Barlow, among others, has, to our knowledge, frequently pointed out that several valves are usually injured in the severe rheumatic carditis of childhood, and in such cases we believe, with others, that it is comparatively common for the tricuspid valve to be affected. The lesions are less severe, no doubt, often indeed very slight, but they are frequently present. Again, when it is remembered that the tendency of these lesions in rheumatism is toward recovery, it may well be that a thickening of the tricuspid segments, really of previous rheumatic origin, may be ascribed entirely, rather than in part, to mechanical overstrain the result of some advanced lesion upon the left side. The question, as it presents itself in rheumatic fever, is one of degree, and to argue that an affection of the right side of the heart, even if severe, *cannot* be rheumatic but is due to a secondary infection is, we believe, to assume more than can be granted. When the extremely delicate valves of the rabbit's heart are affected, the granulations are minute and the distinction between the affection of the valves on the right and on the left side less evident. The aortic segment of the mitral is, however, as in man, a less delicate structure, and it is in that segment that we have noted in addition to granulations some thickening and opacity. It is quite possible that by the experimental method the solution of certain difficulties will be obtained, for just as in man the mitral valve or the aortic may be apparently alone affected, so in rabbits we have observed the same occurrence; yet even in those cases in which only one valve apparently is affected it is quite possible that more than one was infected but that these others have by virtue of the phagocytic action of their connective tissue-cells destroyed the invading organisms which attacked them in comparatively small numbers

At the risk of repetition we would once more state that injury to the tricuspid valve in the severe rheumatic carditis of childhood, though slight in extent, is frequent in its occurrence, and the more carefully it is looked for the more frequently it will be found to occur. That if rheumatic fever is a disease due to an infection there is danger in the assumption that disease of the tricuspid valve is necessarily due to a secondary infection That such may be the case is certain, but how often it is the case yet remains to be proved. Again, when a patient who has been the victim of repeated rheumatic attacks dies from malignant endocarditis it is quite as legitimate to assume that the condition is truly rheumatic though altered in type as it is to assume the occurrence of some secondary infection If the organisms are isolated and demonstrated as specific yet not rheumatic then the position is certain, but to judge by the size of granulations, by the rupture of chordæ tendineæ, by the spread of the vegetations on to the surface of the auricle, or by the marked affection of the tricuspid valve, is, we believe, dangerous and liable to result in an attempt to bind with an iron band a disease which is perhaps of all diseases one of the most variable This fact we can state, that we have succeeded in isolating a diplococcus from cases of endocarditis in which rheumatism appeared to be the only cause, and have reproduced even to the very identical valves malignant endocarditis and then later a condition indistinguishable, as far as the arthritis and endocarditis are concerned, from the condition produced by the diplococcus of simple rheumatism.

The occurrence of ante-mortem thrombosis in the heart in rheumatic fever.—The causes of its occurrence are probably various—there are the mechanical difficulties associated with the valve deformities, there is the weakness of the heart wall, and the increased tendency of the blood to clot. In rabbits the stages of the process can be studied. In one case we noted rapid, feeble, distant heart sounds and the development of a systolic murmur, audible at the lower angle of the right scapula. We were puzzled by the murmur, and suspected, from the condition of the heart, pericarditis. The necropsy showed no gross valvular disease, but a large ante-mortem clot in the right auricle. It is clear that in this case one factor in the causation of ante-mortem thrombosis could be excluded—namely, the mechanical one due to advanced valvular disease. The next case in which we noted the feeble, distant heart sounds we did not wait, but after assuring ourselves that it was not a passing phenomenon the animal was killed and the heart examined. Our conjecture proved correct; ante-mortem thrombosis had commenced in the left ventricle in the neighbourhood of the valve ring beneath the mitral cusps and at the apex of the left ventricle. There was no gross valvular lesion. Finally, as in rheumatism, a mitral systolic murmur may appear early in the illness and then rapidly disappear. So in rabbits we have observed the phenomenon and have ascribed it to the same cause—namely, to an acute dilatation of the ventricle rather than to an organic affection of the mitral valve.

DIPHTHERIA IN SHIREHAMPTON.—At the meeting of the Barton Regis (Bristol) Board of Guardians held on April 26th, Dr. E Crossman, medical officer of health, reported that 25 cases of diphtheria had occurred at Shirehampton during the past two weeks, and he urged the need of further hospital accommodation for infectious disease. The council eventually resolved to build a temporary hospital with 16 beds at a cost of about £550.

A CASE OF PERFORATING GASTRIC ULCER WITH RIGORS.

OPERATION FOR SUTURE FOLLOWED THREE WEEKS LATER BY VOLVULUS AND ACUTE INTESTINAL OBSTRUCTION REQUIRING A SECOND LAPAROTOMY.

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,
SURGEON TO THE ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE; ASSISTANT SURGEON AND SURGEON-IN-CHARGE OF THROAT DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL;
AND
J. F. STEEDMAN, F.R.C.S. ENG.,
LATE HOUSE SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

THE patient, a female, aged 27 years, was seen for the first time on Nov. 10th, 1899, three days before perforation took place. She was then suffering from slight dyspeptic symptoms, without anæmia or marked constipation, and gastric ulceration was not suspected. For two years, however, she had had gastric troubles of varying severity and had once suffered from anæmia. On Nov. 13th at 6 P.M. she had a sudden attack of pain in the left side with vomiting. She rallied from this and when seen on the 14th was fairly comfortable, but had vomited again. During the whole of this day she did not lose ground, and she took a fair amount of hot water and milk diluted with thin barley water. She had a good night. On the 15th she was not so well She had a rigor at 9.20 A.M. The abdomen was tender and tympanitic. Another rigor came on at 12 37 P.M There was no action of the bowels. Mr. Bowlby saw her at 6 P.M., and then, 48 hours after the commencement of acute symptoms, the abdomen was opened by a median incision above the umbilicus. A perforating gastric ulcer was found on the anterior wall and near to the cardiac end of the greater curvature. This was closed with six sutures without difficulty. The ulcer was about a quarter of an inch in diameter, round, with clean-cut edges as if punched out, without any inflammation or inflammatory thickening. The stomach contained about an ounce of mucus, but the abdomen, though distended, did not contain much fluid or solid matter, the latter being chiefly flakes of coagulated milk The spaces behind the liver and Douglas's pouch were carefully sponged out, but the abdomen was not irrigated. A glass tube used to drain the gastro-hepatic region was kept in until the third day after operation. The patient recovered well from the operation and progressed very fairly for three weeks, though the temperature was never quite satisfactory except for a few days at a time. On Dec. 4th, three weeks after the operation, there occurred a sudden attack of very severe abdominal pain with vomiting and collapse. The patient complained of pain in the lower part of the abdomen with some tenderness, and though the pulse was good she looked and felt very ill. The abdomen was distended, especially below the umbilicus, and tympanitic. The liver dulness was almost entirely absent and there was nausea but no vomiting. The pulse-rate was 88 and the temperature was 100° F. Per rectum nothing was felt. From this time till 10 30 P M. the pain gradually increased and the patient became more and more restless. The distension increased and the pulse became more irregular and more feeble, but it was never above 100. At this time the patient was again seen by Mr. Bowlby and it was decided to operate at once.

The operation was performed at 10 30 P.M. by a long incision below the umbilicus. The peritoneal cavity contained about a quart of darkly blood-stained fluid and in the lower part of it could be seen a mass of greatly distended and discoloured intestine. This was firmly fixed down in the pelvis where it seemed to be quite impacted. With some difficulty it was turned out of the peritoneal cavity in a mass, and it was then found that the greater part of the small intestine had been adherent at the bottom of Douglas's pouch and had become completely twisted from left to right so as to form a large volvulus. The adhesions were divided and the mass of distended bowel was untwisted, but was found to be so much distended that two small incisions had to be made with a tenotomy knife to let out gas and fluid before the intestines could be returned into the abdomen. The wounds were closed with Lembert's sutures and the intestines were sponged and returned to the peritoneal cavity. The abdominal wall was sutured in layers and closed. Progress was subsequently uninterrupted and after careful feeding for three weeks the patient made a satisfactory recovery.

The case is interesting from several points of view, not least on account of the extraordinary vitality and recuperative power of the patient who survived two days of peritonitis following perforation and the necessary operation for suture as well as the strangulation of an immense quantity of small intestine and a very serious operation for its relief within three weeks of the first abdominal section. The conditions found at the second operation are fortunately rare and the adhesion of the intestine was evidently the result of inflammation of the pelvic peritoneum, the volvulus occurring secondarily to the adhesion and being the result of the attempts of the bowel to escape from the band, whilst the band itself by forming a fixed point enabled the twist to occur. As in all such cases the incisions into the bowel were of great service in permitting the replacement of the distended gut and in helping it to recover subsequently.

The symptoms before the first operation were also very unusual and misleading. It is certainly very rare for rigors to occur after perforation of a gastric ulcer, but in this case they were very severe and were accompanied by great pyrexia, the temperature at one time reaching 106°, while the pulse never became really rapid.

At the time of the occurrence of the volvulus, also, the pulse remained below 100, in spite of the strangulation of a large mass of intestine, and although the patient was evidently much collapsed and in intense pain. It is seldom that so serious a condition as was found in this case on opening the abdomen causes so little disturbance of the pulse-rate, but this case, and others which we have seen, should serve as a warning not to place too much reliance on a quiet pulse where the question of laparotomy is under consideration for the relief of such suspected conditions as perforated gastric ulcer and volvulus.

ON SEROUS VACCINIA IN CONNEXION WITH CRETINISM AND RICKETS.

BY ROBERT KIRK, M.D. EDIN., F.F.P.S. GLASG.,
PHYSICIAN TO THE DISPENSARY FOR DISEASES OF WOMEN, GLASGOW WESTERN INFIRMARY.

THE serous character occasionally manifested by vaccine lymph is generally recognised to be of constitutional origin in the majority of cases, but, so far as I am aware, its connexion with cachectic states which may develop subsequently has not received much attention, whence there is reason to hope that the following cases may prove of interest.

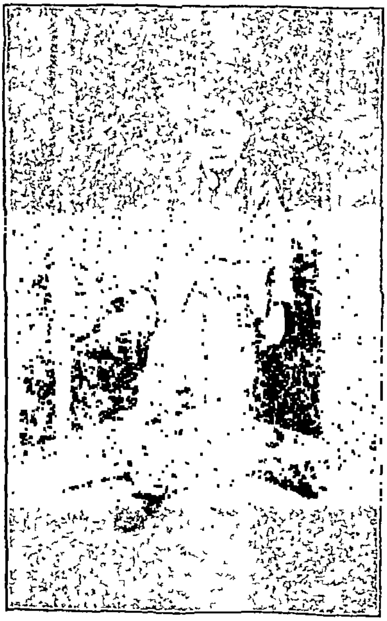
CASE 1. *Serous vaccinia; myxœdema at the age of 34 years.*—This patient, an unmarried female, 40 years of age, the sister of a congenital cretin whose case was reported in 1884,[1] became herself myxœdematous at the age of 34 years. Shortly before or during the early stages of myxœdema she displayed great susceptibility to the action of primula obconica on the skin and experienced several attacks of dermatitis attended with an eruption of bullæ, which yielded a copious flow of thin watery serum, from the mere handling of this plant[2] Her mother states that as an infant she had been extremely liable to become blue on exposure to cold, this being a feature common to most of the cases which follow. Of her vaccination it may suffice to state that lymph was taken from the arm on the eighth day and that it continued to flow freely from it afterwards during the whole afternoon, while both the first and second scabs which formed emitted serum copiously. On the day after the opening of the vesicle (one large insertion had been made) increased redness and swelling supervened, and the former extended from the back of the hand to the left ear, this condition lasting for 10 or 12 days, during which the child was extremely irritable, although her health was not injuriously affected afterwards It is of interest to add, as showing that there were no germs other than those of vaccine in the lymph, that a neighbour vaccinated her own baby from it after the medical man had left and a perfect vesicle resulted which gave no trouble. I may here mention that in the brother of this patient, the congenital cretin already noticed, the vaccine lymph did not manifest the serous character and the same is to be said of another congenital case (a remarkable combination of cretinism and rickets) which I have had under observation. I refrain from commenting on this negative fact in the present article.

---

[1] THE LANCET, August 23rd, 1884, p. 314.
[2] THE LANCET, March 4th, 1899, p. 579.

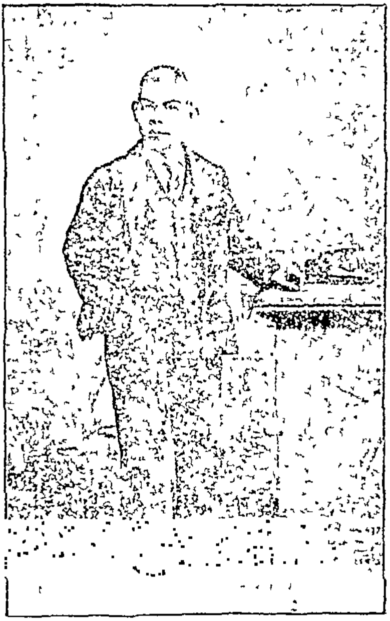
CASE 2. *Serous vaccinia; subsequent cretinism or juvenile myxœdema.*—In this case there can be little doubt that the sequelæ of vaccination led to acquired cretinism, although probably in a predisposed subject, this, I believe, being the first case of the kind recorded. The patient, a young man in his twenty-second year, first came under observation more than a year ago when his height was 4 feet ½ inch and his weight was 5 stones. Of his family history I may only mention that his mother, who died at the age of 47 years, was perhaps myxœdematous, as she was for some years very stout and supposed to be dropsical and is said to have had "a skin like wax and cheeks like roses." The patient's case, when he first came under notice, was a good illustration of what French writers have called *la forme fruste du myxœdème atrophique*[3] and was remarkable for certain negative features; for instance, there was no slowness or other defect of speech, so that when I first showed the patient to the Medico-Chirurgical Society of Glasgow (on March 17th, 1899) the diagnosis of cretinism was generally doubted, and several members expressed themselves strongly against it.[4] Thyroid treatment was commenced on May 13th, 1899, and when the patient was again brought before the Society (on Feb. 2nd, 1900) his height was 4 feet 5¼ inches. At this meeting the President (Dr G. S. Middleton), and Dr. A. G. Faulds suggested that it would be of interest to see the developmental state of the osseous system in the case, and to the latter, who has done some good work with the x rays at the Glasgow Royal Infirmary, I am indebted for a skiagram of the hand and forearm with regard to which he observes in a note that "the bones are in a state of incomplete ossification with non-union of diaphyses and epiphyses similar to the condition seen in a child 11 years of age." This is analogous to what has been observed by Hofmeister and von Eiselberg in the experimental myxœdema of newly-born animals to which the president referred at this meeting.[5] Fig. 1 and Fig. 2 represent the patient as he appeared (Fig. 1) before treatment and again (Fig 2) after he had grown to the height of 4 feet 6½ inches (in May last). In these the relative difference in height is closely preserved. At the date of writing (November, 1900) his height is 4 feet 8¼ inches, so that it will be observed that he has not been growing so rapidly of late.

FIG. 1.



Before treatment.

FIG. 2.



After treatment.

At neither of the above meetings did I refer to this patient's vaccination, this being a subject which I reserved for further observation. The following is a brief account of it derived from statements made by his eldest brother and other relatives. His mother took him to a public institution in this city for the purpose and she afterwards described the operators as being very careful, remarking that they examined behind the ears, the buttocks, &c. She also saw the vaccinifer, from whose arm a number of other infants were vaccinated at the same time, and confessed that it was a fine healthy child, with a beautiful "pock." Six insertions were made and all "took" and from all the six vesicles resulting lymph was taken on the return day. Lymph continued to flow freely from the arm after the mother left the dispensary, and next day redness and swelling supervened and extended by-and-by to the knuckles and the top of the shoulder, and this condition is said to have lasted for two or three weeks. The vesicles meanwhile continued to discharge serum, while the subsequent scabs are said to have done so for several months altogether. Strange as it may seem, the mother did not take the child back to the dispensary and did not call in a medical man till some weeks had elapsed, when the case proved refractory, for the arm was not completely healed for 18 months. From the time of his vaccination the child grew always very slowly, and the height which he finally reached when first seen, at the age of 21 years (4 feet ½ inch), was all completed before he was 10 years old. The unfortunate result in the case was evidently due to gross neglect and mismanagement, but I am here only concerned with the serous character of the vaccinia in its early stages, and as bearing on the constitutional origin of this feature the cases in the following family seem to be of special significance.

[5] Centralblatt für Anatomie und Pathologie, 1893, p. 353.

CASE 3. *Serous vaccinia in six members of a rickety family of seven children; cretinism in one child.*—The parents in this case were both alive in September last, when the mother died from aneurysm of the aorta and profound anæmia at the age of 66 years. The father is 71 years of age and of the children only three survive, of whom the cretin is one. He is the youngest of the seven and was a healthy child until the age of two years and four months when he was suddenly seized with croup of so violent a type that on the first day of the attack he was apparently suffocating, with crowing inspiration, &c. The medical attendant ordered leeching followed by poulticing; five leeches were applied and the poultices drew a large quantity of blood, leaving the patient ghastly pale. The dyspnœa was instantly relieved and it never returned, and although for a few days the child seemed to be dying he gradually recovered, but only to lapse at once into his present condition of complete cretinism. He is now 26 years of age, is bandy-legged, 3 feet 2 inches in height, and 3½ stones in weight. He has an extremely thin and delicate skin, showing the veins clearly in many places, although rough and scaly in others, a scrofuloderm (besides pseudo-lipomata) in the neck, and two cicatrices over one knee-joint, the remains of a chronic abscess from which he had suffered for many months. The mother had also a similar abscess at one time about the knee, and the entire family betrayed evidence of a marked proclivity to scrofula and (the children at all events) to rickets. On inquiry I ascertained from the mother that vaccinia had manifested the serous character in every member of this family but one, the eldest son, who was not rickety, is still surviving at the age of 36 years, but is now probably phthisical. In all the rest the sites of vaccination had discharged serum for several weeks, although in four of these the vesicles were not opened by the operator but ruptured spontaneously, and this in spite of the fact that one had only one, and another two small vesicles, and that the mother took every precaution to avoid this mishap. This spontaneous rupture happened in the case of the cretin and the only other survivor (also a son); this latter, about 34 years of age, is a pronounced example of rickets and is barely five feet in height, with a disproportionately large head; he did not cut his first tooth till the age of 18 months and could not walk till his seventh or eighth year. In the case of one child, a girl who died at the age of 18 months, the vaccinated arm, after rupturing spontaneously and discharging thin serum for a week or more, became affected by some inflammatory condition, apparently a form of lymphangitis, which extended to the corresponding side of the trunk and, as the mother believes, so undermined the child's health that she never fully recovered from the effects. She describes her as having had blue veins and a delicate skin, and as being very apt to turn blue with cold. She even attributed injurious results to vaccination in other instances, and there seems to be no doubt that vaccinia of this character may readily become the parent of other evils if not promptly and judiciously treated. It is surprising that this form of the affection is not mentioned in some recent works on vaccination or in the final report of the late English Royal Commission.

CASE 4. *Serous vaccinia with symptoms probably indicative of a myxœdematous tendency; spasmodic asthma at the age of six years.*—This patient, a boy aged seven years, was recently brought to me by his mother, an intelligent woman, who reported that of late he was easily tired and did not care to exert himself and frequently complained of sore legs, especially on walking up-hill. She had already regarded him as "delicate" and she said that as a baby he had had a pink-and-white skin and that his face and hands got cold readily. At the age of five years he had an attack of whooping-cough, which clung to him for months, and within the last 12 months he had had frequent paroxysms of an asthmatic character, in one of which I had lately the opportunity of seeing him. Without inquiry on my part the mother adverted to the subject of his vaccination and she drew a picture of a type of serous vaccinia which every experienced vaccinator would at once recognise, so that I need not enter into details. I may add, as a fact not without significance, that I found this lad very easily blistered by a slight application of iodine liniment.

I can here only glance at some conjectures and opinions which I have been led to entertain with regard to the questions suggested by this subject. The records of cretinism (or myxœdema) and facts observed in my own cases have strongly impressed me with the view that constitutional factors play a predominant rôle in the causation of this cachexia, and it would appear that we might sometimes recognise the predisposition to it in infancy by the physical signs and symptoms manifested in some of the above cases, and these, it will be observed, are the same as were formerly assigned to a certain category of the scrofulous. An important fact in favour of this view of the etiology of the disease is the occasional occurrence of more than one case in the same family. The inherited constitutional vice seems to be a common source of various other forms of degeneration and disease, depending probably on the incidence of different exciting causes; thus, besides serous vaccinia, I have encountered in myxœdematous subjects and other members of the families to which they belong instances of blindness, deafness, mouth-breathing from nasal obstruction, tuberculosis, and rickets, besides such neuroses as spasmodic croup and spasmodic asthma (a notable example of the latter being a brother of the patient in Case 1). Passing over other problems I would here limit attention to the question: Is the thyroid specially concerned in the production of serous vaccinia and serous types of other affections? Briefly I would answer that the evidence seems to show that such is the case in many instances, although it would be hard to speculate on other factors which may sometimes coöperate. It would appear, further, that the condition of the gland in such cases is one in which it is prone to atrophy from exciting causes which would otherwise prove inefficient. The identity of the effect, so far as serous exudation is concerned, produced in Case 1 by vaccination and by the action of primula obconica and the subsequent development of myxœdema in the case seem to be facts of much significance. It would appear that we ought to recognise the existence of a serous as emphatically as we do that of a hæmorrhagic diathesis, and it is probable that the two are intimately related to each other, while it is evident that both are associated with great vulnerability of tissue by various morbific agents. Thyroid treatment has proved of value in hæmophilia and some of the other affections which have been here clinically grouped together, and quite recently I had a case of nasal hydrorrhœa of three years' duration in a girl, aged 12 years, which was promptly arrested by it. This is conclusive evidence if corroborated by further experience.

It has been concluded from experiments by Schiff and Horsley that the thyroid has an antitoxic action on certain toxic substances resulting from the digestion of albuminous bodies, and I would further ask, Is it possibly concerned also in defending the organism against the germs of some zymotic diseases? If the healthy gland is necessary to produce the viscid lymph of normal vaccinia it is readily conceivable that it may perform an office of this defensive kind, whether it has any toxin-destroying power or not. For lymph of a certain degree of viscidity may act as a bulwark of defence, limiting, perhaps, the multiplication of organisms and the amount of toxins produced and absorbed, whereas when it is of the serous character opposite results may ensue. I venture to submit, not without hesitation, a suggestion on this subject. It is that vaccination and perhaps experiments on vesication should be performed on calves and a few other animals after extirpation of the thyroid. It seems probable that the greater viscidity of calf lymph as compared with human lymph may be due to greater energy of the thyroidal function, this being probably necessary to maintain the higher temperature and more rapid growth of the calf. When we further reflect on the profound changes effected in experimental cachexia strumipriva, the diminished coagulability of the blood, and the leucocytosis and anæmia, as described by Halliburton and Horsley,[6] it is not unreasonable to suppose that some modification in the course of vaccinia or in the character of the lymph produced might be observed. And, if any such should be found to occur, experiments on variolation might be once more tried in the same condition of the bovine animal.

Glasgow.

[6] Report of the Committee on Myxœdema.

THREE CASES OF SARCOMA OF THE UTERUS.

By E. OCTAVIUS CROFT, M.D. Durh.,
HONORARY SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, LEEDS; DEMONSTRATOR OF OBSTETRICS IN THE YORKSHIRE COLLEGE, LEEDS.

Primary sarcoma of the uterus is undoubtedly a very uncommon disease, but in all probability its rarity is considerably over-estimated. Such a large number of cases of malignant disease of the uterus come under observation only when the disease is so far advanced that anything more than palliative treatment is impossible and therefore a careful pathological examination of the nature of the growth is not made and it is possible that many of these cases may have been of sarcomatous rather than of carcinomatous malignancy.

Mr. Roger Williams in his recent book[1] states that his analysis of 2649 consecutive cases of primary uterine neoplasms comprises only two examples of sarcoma to 1571 cancers He does not state whether these were all confirmed pathologically, but I presume that they were. Recently, however, interest has been aroused in this disease and cases are being recorded more frequently. The following cases are therefore, I think, worthy of reporting, especially as they exemplify three very distinct varieties of the disease both in their clinical and pathological features.

Case 1.—The patient was a married woman, aged 39 years, who had had one child and who had had no abortions. Menstruation, which commenced at the age of 14 years, was regular, copious, and not very painful. The patient was married in 1893. About six months after her marriage the menstrual flow increased and she was operated upon for something which was said to have protruded from the vulva when she strained. In 1895, the menorrhagia having returned, she came under my care at the Hospital for Women and Children at Leeds and I found and removed several polypi from the cervix and the uterine cavity which was scraped. These growths had all the appearances of ordinary mucous polypi. The condition of the patient so far improved that a few months afterwards pregnancy occurred and her only child was born after a normal labour at the end of 1896. About six months after confinement and on two subsequent occasions some polypoid growths were treated by various surgeons, on the last occasion the operation being stated to have been radical. On May 13th, 1899, the patient returned to the hospital for urgent bleeding and severe anæmia. The uterus was found to be enlarged and a polypoid mass of growth of about the size of a fist occupied its cavity. This was scooped away and the cavity was cleansed and packed with gauze. It was then found that there was a further growth in the left wall of the uterus. Examination of the tissue which had been removed proved it to be undoubted sarcoma. When her general condition had improved ether was given with a view to radical operation if found possible. It was then found that in addition to the growth in the uterine wall a further large mass existed burrowing deeply between the layers of, and at the base of, the left broad ligament. It also extended upwards above the brim of the pelvis and was closely related to the bladder in front and the rectum behind. The disease was clearly irremoveable. The growth then slowly increased and occasional attacks of bleeding required treatment by packing. The patient's health steadily failed. Twelve months afterwards she was again in the hospital, the discharge, which had become foul, having produced septic symptoms. The growth was then found to have increased greatly. A large mass occupied the lower half of the abdomen, three rounded masses being especially prominent. One of these could be identified as the uterus enlarged with an intra-uterine mass. The sepsis was relieved, but the patient gradually became weaker and she died from exhaustion in September, 1900. A noticeable and fortunate circumstance in the case was an almost entire absence of pain throughout. There were no symptoms or signs indicating the presence of secondary growths in other organs.

The nature of the growth, which was examined on several occasions, proved to be an undoubted round-celled sarcomatous infiltration of the uterine tissue. There was no evidence of any structures in the specimens which might suggest the case to have been one of deciduoma malignum. The fact, however, that the polypi which were removed before the pregnancy were apparently innocent and that the malignancy of the disease asserted itself a few months after confinement is a point of great interest. If the exact nature of the growth had been ascertained on its recurrence after the confinement it is possible that a radical operation (hysterectomy) at that time might have saved the patient. The condition was only discovered when secondary growths rendered operation impossible.

Case 2.—The patient, a widow, aged 66 years, was the mother of four children Her last confinement had taken place at the age of 40 years. The menopause occurred naturally in her forty-sixth year. For seven or eight years there had been a slight, occasionally blood-stained, discharge from the vagina, but this discharge had become much increased during the last few months. She complained of very little pain until about six weeks before I saw her, but during that time the pain in the lower abdomen had been severe. There had been marked loss of flesh recently. On examination there were great pain and tenderness in the hypogastric region, so much so that thorough examination was impossible. Vaginal examination revealed a patulous cervix free from disease, an enlargement of the uterus, and an offensive blood-stained discharge issuing from its cavity. The patient was examined under ether The uterus was then found to be generally enlarged, its fundus reaching two or three inches above the pubes, and there was evidently some peritoneal effusion and adhesion. The interior of the cavity of the uterus was found to be roughened and irregular with new growth which was specially abundant near the fundus. This part was necrotic and it easily broke down. Owing to the presence of the peritonitis and the general condition of the patient extirpation was impossible. The uterine cavity was cleansed as far as possible of foul tissue and was packed with iodoform gauze. Portions of the growth were preserved for examination. The patient did not improve and eventually she died from the peritonitis.

The growth consisted of a very vascular sarcoma consisting of bundles of spindle cells with many vessels and much blood. It is probably an example of the diffused sarcoma of the connective tissue of the uterine mucous membrane.

Case 3.[2]—A married woman, aged 32 years, the mother of four children, was sent to me in June, 1898, by Dr. C. J. R. McLean of Yeadon for metrorrhagia following the expulsion of a vesicular mole. Menstruation, which commenced at the age of 14 years, was never regular, the flow appearing about every six or eight weeks and lasting for two or three days. It was then scanty and painless. The patient had married when she was 26 years of age, and having had four pregnancies in rapid succession and three of the infants having been suckled menstruation was practically absent during the whole of this period The labours were all difficult. The second child was delivered stillborn with instruments. The fourth and last child was born two years before I saw her and she had never been well since, but always anæmic and weak. The child was suckled for 18 months, and soon afterwards menstruation returned two or three times and then followed a flooding. The uterus then rapidly enlarged, and the flooding recurring a vesicular mole was diagnosed and the uterus was cleared by Dr. McLean. The uterus shrank and the bleeding ceased, but a watery discharge continued, increased, and became offensive and occasionally bloody. When sent to me the patient was extremely anæmic and her temperature was 103° F. The os was patulous, the cervix was soft, and the uterus was enlarged, the sound passing three and a half inches, and freely moveable. Under ether the uterine cavity was explored. The finger detected a rugged friable mass attached to the upper and posterior part of the uterine wall. It gave the impression of a malignant growth. The free portions were carefully removed with a scoop and the cavity was irrigated and packed with iodoform gauze. The growth was preserved for examination. The septic condition subsided and the patient improved. The growth was examined independently by several pathologists who all agreed that it was sarcoma,

---

[1] Uterine Tumours, 1901.

[2] The specimen from this case was shown at a meeting of the Leeds and West Riding Medico-Chirurgical Society in October, 1898.

The report of the Clinical Research Association was to the effect that the tissue consisted of uterine muscle substance infiltrated with sarcoma. The cells were spindle-shaped and many of them were very large. The characters of the growth were not like those of deciduoma malignum. The uterus was consequently extirpated by vaginal hysterectomy and the patient made a good recovery. I examined the patient a few months ago—that is, just two years after the operation—and I found her to be free from disease and in good general health. I have recently heard that she continues well.

The uterus when removed showed no signs of growth externally. On opening its cavity by a vertical incision through the anterior wall the disease was seen to consist of a small, reddish, lobulated sessile growth situated on the upper and posterior part of the uterine wall and projecting towards its cavity. The other portions of the uterine wall presented no naked-eye evidence of disease. Further microscopical examination of sections direct from the growth after removal confirmed the previous diagnosis.

Leeds.

A CASE OF RECOVERY AFTER OPERATION FOR DIFFUSE PERITONITIS FROM PERFORATION OF THE APPENDIX

BY RUSSELL COOMBE, M.A., M.D. CANTAB., F.R.C.S. ENG.,
SURGEON TO THE EXETER DISPENSARY.

THE case which I have described below may prove of interest when read in conjunction with the case reported by Mr. Charles A. Morton.[1] The infection was obviously widespread, as in that case, but I acted in the operation on the belief that the upper part of the general cavity was free and that it was my business to leave it so. On the other hand, the pelvic part of the cavity was full of dirty fluid, which was most thoroughly sponged out and the cavity drained. The consecutive abscess in the left scrotum was doubtless due to a patent funicular process on that side.

On March 1st, 1901, I was asked by Dr. A. Macindoe of Sidmouth to see a patient a boy, aged 14 years. The past history of the patient was unimportant, there being a record of an occasional stomach-ache but nothing more. The boy was perfectly well on Feb. 25th. On the next morning he had some pain which he referred to the region of the appendix. He felt sick and had lost his appetite, but he sat up all day. He was first seen by Dr. Macindoe's locumtenent on the morning of the 27th. He had had some shivering during the night and had begun to be sick, with severe abdominal pain which had kept him awake all the night. The vomit was at first bilious, becoming darker afterwards. The bowels had acted. The abdomen was distended, more especially on the right side. The temperature was 104° F. Dr. Macindoe first saw him on the 28th. He was still very sick and the abdomen was much distended.

I visited him late in the afternoon of March 1st when the sickness had stopped, but the boy was obviously very ill. His temperature was 102°, his pulse was 132, and his respirations were 36 He had a hard, dry, red tongue with moist edges, and the respiration was chiefly thoracic. The lad lay on his side with his legs drawn up. The abdomen was generally swollen but it was very markedly so in the neighbourhood of McBarney's point, there being already some redness and œdema in that situation. It was impossible to operate that night, but as early as possible on the next day (March 2nd) I opened the abdomen by an oblique incision reaching as far down as the deep epigastric vessels. On dividing the peritoneum at the upper part of the wound I at once came on an abscess extending upwards outside the ascending colon towards the liver. The pus, which had a strong fæcal odour, was carefully sponged out of this. The edge of the omentum, which lay on the inner side of the wound between the large bowel and the parietes, was not disturbed at the upper part, as there was a little glueing together of the peritoneal surfaces, but in the direction of the pelvis there was not the faintest attempt at any barrier and the fingers passed right down into the pelvis to the roof of the bladder, a large quantity of dirty brown-tinted blood welling up as the coils of intestine were separated. This fluid was sponged away as it welled up, and when this ceased the sponges were continually passed down into the pelvis until they returned dry. Two large drainage-tubes were then inserted, one going to the sub-hepatic pouch, the other down into the pelvis. The appendix itself was not seen.

The after-treatment was simple. Half a grain of calomel every hour for eight hours and a rectal tube did wonders in relieving the abdominal distension. A concretion of the size of a butter bean came away from the upper part of the wound on March 27th, the wound healing entirely a few days later. The only drawback during convalescence was that on the third day after the operation the scrotum became inflamed and an abscess slowly developed in the left tunica vaginalis. This was opened on March 13th and about three ounces of very foul pus escaped. The boy is, I hear, now about and well.

Exeter.

ON THE USES OF DIPHTHERIA ANTITOXIN.

BY T. B. BROADWAY, M.B., B.CH. GLASG.

AT a time when the antitoxin treatment of diphtheria is still in its infancy, when there are many who use it doubting its value—hence tardily and inefficaciously—and still a few who have no faith in its efficacy whatever, the putting in black and white of the successful cases that have occurred in the hands of those who have used the serum may help to its getting a fair trial and may be the means of not only saving the lives of patients, but of cutting short the attack and hence saving the patient from many of the sequelæ that follow. From October, 1898, to October, 1900, I have treated about 30 cases of this disease, the oldest patient being a child aged 13 years, and the youngest a child aged two years, and with the exception of half-a-dozen were treated with the antitoxin, the result being that of those treated with it only one of the number died, whereas of the six patients treated along the ordinary lines two died and two developed post-diphtheritic paralysis. The two latter unfortunately neither at the time nor at any time of the treatment showed a membrane, and I treated them for a simple angina of the throat, and it was not till the paralytic symptoms developed that it struck me that they had had diphtheria. These two cases were also the starting-point of an epidemic. In one case paralysis affected the limbs, whereas in the other case the thoracic muscles and the muscles of deglutition seemed to be especially affected; there was some loss of power in the arms, but the lower limbs seemed to escape altogether.

In the case treated with antitoxin that resulted in death the patient was seen by me first on the third day of illness. He was 11 years old and at the time when I saw him he had difficulty in breathing and in swallowing. On examining the throat I found a membrane, somewhat greyish in colour, covering the naso-pharynx, tonsils, and uvula, with an offensive discharge from the nares and enlargement of the glands of the neck. After carefully washing the lumbar region with turpentine, rectified spirit of wine, and perchloride of mercury (1 in 1000) I injected 2000 units of the serum obtained from Burroughs and Wellcome and at the same time ordered inhalations of carbolic acid. On calling again I found the boy much easier in his breathing and his father told me that he had been able to swallow his milk more easily and, in fact, was constantly calling for some. On examining the throat I found the membrane greatly reduced. I then again injected 1500 units of the serum and after leaving injunctions that the boy was on no account to be allowed to sit up left with the full conviction that he would do well. Soon after my leaving he coughed up the membrane and slept soundly, but unfortunately on his father leaving the room he sat up and tried to help himself to some milk and fell back dead, death being due to cardiac failure. This was a lesson to me in giving a prognosis, and in all my other cases I took care to place the patient on a cardiac stimulant, the one generally used being a mixture containing two drachms of solution of perchloride of iron, one drachm of solution of strychnia hydrochlorate, with glycerine and water to six ounces; one or two drachms every four hours. To this and also to the care which I took in explaining to the parents or nurse of the child the reasons for keeping the patient as still as possible I think I owe my success in serum treatment.

In aborting serious symptoms serum again holds the field. In the case mentioned it cut short the dyspnœa and allowed the patient to swallow with ease; in other cases, and especially in one, I noticed the great relief produced soon after the injection of the serum. In this case the child was two years old and had been ill for two days previously to my seeing her. When I arrived I found the child flushed in the face, tossing about with a short, constant, hacking cough; as she was only two years old I could elicit nothing from her, so I had to trust to my observations and the mother's statements. I found that the temperature registered 99 6° F. I tried to examine the throat, [illegible] to the restlessness of the chi [illegible] angle of the jaws enlarged. T [illegible] could not "clunk" (swallow) her food with ease and also that she had two or three attacks of croup for which she gave her ipecacuanha wine, but without much benefit; she further stated that the child had had practically no sleep for the past two days. After carefully cleansing the part I injected in the gluteal region 1500 units of serum and waited to see its effects. In half an hour I found that the temperature had risen about a degree—that is, it registered 100 6°. I then left and called again in the evening, when the mother told me that the child was sleeping and that she had practically slept from the time I left in the morning; in fact, it made her a little nervous. I now found the child's temperature to be 99°, but as there still seemed to be some difficulty in swallowing I gave her another injection of 1500 units of serum and left. On the next morning I found that the patient had passed a fair night and had taken a good quantity of milk; her temperature, however, was 99 8°, so I gave her another injection of 1500 units of serum. I did not see the patient again till next morning, when her temperature was 98°, and as she also seemed to be fairly well otherwise I did not give her any more injections but put her on one drachm of compound solution of phosphate of iron every four hours. The patient did very well.

Space prevents me from giving a description of the other cases, but what I wish to impress on all is, first, that the serum treatment of diphtheria has placed the prognosis of this disease in a more favourable light and if used early practically saves life; secondly, it preserves the patient from the serious sequelæ that often follow recovery from it; thirdly, if proper antiseptic precautions are taken no abscesses form at the seat of injection; and lastly, the almost instantaneous relief which it gives to very distressing symptoms would alone justify its use, especially in a country practice where often medical help for a tracheotomy is hard to procure. Probably the injection of a saline solution at the same time as the antitoxin, as advocated in THE LANCET by Dr. E. E Laslett,[1] would add to its efficacy.

In very young children I found the gluteal or interscapular region the best for injection; in older ones I often injected into the loose tissue of the breast, but when the child showed dread of the operation I injected into the gluteal region instead. The chief difficulty which I found in using the serum was the prejudice of the parents, and as, unfortunately, they usually belong to the illiterate and unthinking class it is hard to reason them into believing in the serum, though when they do allow its use and see the good which it does they are the very class to carry its praises far and wide.

In closing I would add that to procure good results from the serum it should be used early, *freely*, and in all doubtful cases of sore-throat, for even if it is not diphtheria the serum will give rise to no bad results. To wait till the diagnosis is confirmed by bacteriological examination is throwing away precious time. A swab should be sent for examination, but at the same time the serum should be used. I may here add that I found it beneficial to give some simple mouth-wash or gargle, such as boric acid, chlorate of potash, and glycerine, as it helped to keep the mouth, &c, fairly sweet. An inhalation of formic aldehyde, carbolic acid, or turpentine helped to check the spasmodic cough which is often so troublesome.

St. Dennis, Cornwall.

THE RESPIRATORY MOVEMENTS OF THE PRÆCORDIAL AREA IN HEALTH AND IN DISEASE.

BY J AIKMAN, M.D. GLASG.

FOR about two years I have given some attention to certain modifications of the chest movements during the respiratory act in the region known as the præcordial area. These modifications seem to indicate acute or chronic disease and also to forecast the advent of it. In the hope that my observations may offer a useful guide in practical work I venture to call some attention to their detail.

Normal.—Anyone who will carefully compare the third intercostal space on the left side with that on the right may convince himself that the left intercostal space rises and falls at its sternal end during the respiratory act to an appreciably less degree than the right. He will become cognisant that the area of limited *movement is very small* It does not extend to the left beyond the junction of the cartilage to the rib. It does not usually extend upwards to the second intercostal space except in young children, but it does extend to the fourth intercostal space, and below that it is masked by the apex beat. I think that in children the cartilages of the ribs show lessened movement over the præcordial area, but the intercostal spaces show it more markedly. The comparatively still area is only discoverable in the normal chest when care has been taken to place the patient in a perfectly normal position He should lie flat on his back in bed, his head should be straight, his shoulders and hips square, his legs straight, and his arms laid along his sides. In a twisted position the condition is not obvious. Lateral curvature of the spine masks it. So does rachitic deformity of the chest. This remark applies to all information which can be gathered from the respiratory movements.

In pericarditis.—While watching the respiratory movements during the course of acute rheumatism I have found that a marked diminution of the movement in the third left intercostal space precedes the stethoscopic signs of pericarditis by a period varying from one day to four days. In a much shorter period the limitation of movement extends to the second, and even to the first, intercostal space, and increases, less markedly, to the left. By this time both the costal cartilages and the intercostal spaces are involved, but there may be neither extension of the dull percussion note nor friction sound. I have never been disappointed in my expectation to find both at a later date. So far I have never waited more than four days but more often I have found conclusive evidence after one or two days. Continued observation of such cases has taught me that this limitation of chest movement disappears with recovery and reappears as a prognostic sign of relapse. Should these observations be verified by other hands they ought to have some bearing upon treatment.

In endocarditis.—The variations of chest movement which prognosticate and evidence endocarditis are less in degree. They are least marked when the right side of the heart is involved but I have been able to distinguish them. Their extension is less upwards and more outwards. The downward extension is attended by a displacement of the apex beat. I have also noted that the return of movement follows more slowly the diminution of stethoscopic signs and that some limitation remains as a record in cases where permanent damage is done.

The result of a careful examination of many cases of old-standing cardiac disease with compensatory hypertrophy or dilatation, convinces me that the præcordial stillness is wider than normal. The explanation may be identical with that of normal stillness—the indication may be the physiological record of a pathological fact. I have recently noted the same phenomenon previously to death from ante-mortem clotting.

These observations have been checked by some of my professional friends—Dr A. S. Dick (now of Glasgow) and Dr. R. Scott Frew who is working with me at present.

When Dr. W. J. Collinson was appointed house physician to the Royal Berks Hospital, Reading, I put the subject before him and asked him to observe. I quote his cases rather than my own, as they give the records of an independent observer. He writes under date Feb. 26th, 1901:—

> Only five cases of rheumatism came into hospital free from cardiac trouble. Of these five, three developed cardiac symptoms, and in each of them the sign of which you told me was well marked.
>
> No. 1, Mrs. ——, admitted Oct. 20th, 1900. Heart normal; expansion of chest normal. Oct. 21st: deficient expansion on left side. Oct. 24th: systolic murmur heard in mitral and pulmonary areas. Subsequently disappeared.
>
> No. 2, —— ——, aged 18 years, admitted Nov. 26th, 1900. Heart sounds and chest expansion normal. Nov. 29th: deficient expansion on left side of chest. Nov. 30th: systolic murmur in pulmonary area. Jan. 15th, 1901: systolic murmur in pulmonary and mitral areas.
>
> No. 3, —— ——, aged 19 years, admitted Jan. 28th, 1901: heart sounds and chest expansion normal. Jan. 31st: deficient expansion of left chest. Feb. 2nd: heart sounds faint, no murmur (myocarditis). Feb. 5th: well-marked pericardial friction. This patient died and pericarditis, endocarditis, and myocarditis were found post mortem.

It seems to me incredible that this sign should not have been previously recorded, but I know of no such record. I advance it for the consideration of the profession in the belief that it will prove true and useful.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE RESULTS OBTAINED BY THE ANTI-TYPHOID INOCULATIONS IN EGYPT AND CYPRUS DURING THE YEAR 1900.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

I AM indebted to the kindness of Colonel W. J. Fawcett, R.A.M.C., Principal Medical Officer in Egypt, for the following statistics dealing with the incidence of enteric fever and the mortality from the disease for the year 1900 in the inoculated and uninoculated among the British troops in Egypt and Cyprus.

—	Average annual strength.	Number of cases of enteric fever.	Number of deaths from enteric fever.	Percentage of cases calculated on average annual strength.	Percentage of deaths calculated on the same basis.
Uninoculated ...	2669	68	10	2·5	0·4
Inoculated... ...	720	1	1	0·14	0·14

These figures testify to a nineteen-fold reduction in the number of attacks of enteric fever and to a threefold reduction in the number of deaths from that disease among the inoculated.

In a note appended to the statistical table printed above Colonel Fawcett observes that the measure of protection resulting from the inoculation is not fully disclosed by a comparison of the figures of cases and deaths given in the table. Owing to the circumstance that soldiers inoculated in previous years are in the statistics included among the uninoculated, the number of the uninoculated was in reality less, and the number of the inoculated was in reality greater, than the figures set down for these groups in the first column of the above table. The figures in the second and third columns, on the other hand, accurately represent the number of cases and deaths in the inoculated and uninoculated, inasmuch as none of those inoculated in previous years contracted enteric fever.

A further point adverted to by Colonel Fawcett is that the only case which occurred among the inoculated occurred in the case of a patient admitted to hospital on the thirty-third day after inoculation. It would seem that the disease was in this case contracted before anything in the nature of protection had been established by the inoculation.

Netley

PRIMARY LARYNGEAL DIPHTHERIA.

BY E. M. SPENCER, L.R.C.P. & S. EDIN., M.D. TORONTO.

THE case of suspected laryngeal diphtheria published in THE LANCET of April 6th, p. 1009, by Mr. A. De Winter Baker induces me to send a short note of a very similar case, but one in which laryngoscopy was available leading to a positive diagnosis. On March 17th, 1901, I was called in to see a boy, aged 14 years, who was said to have a "cold." I found the patient dressed and, with the exception of slight hoarseness, seemingly not very unwell, with a pulse of 104 and of good volume, and complaining merely of slight sore-throat. A careful survey of the pharynx revealed nothing but a little hyperæmia of the fauces, and I made a diagnosis of slight laryngitis and expected the patient to mend soon. On the following day, however, I received a message that the boy seemed very "bad in his throat," and on my second visit he was suffering from constant slight dyspnœa with occasional exacerbations of urgent distress, accompanied by great excitement and cyanosis. There was now complete aphonia. Inspection of the pharynx revealed nothing but the slight redness noticed before. There was marked stridor on auscultating the trachea which became very loud on the accession of an attack of "suffocation" which was doubtless partly spasmodic. I inquired as to the possibility of lodgment of a foreign body, but this was negatived. Seeing that the case was urgent and rapidly growing worse I had the patient removed to my house for purposes of examination. Laryngoscopy revealed firstly great redness and swelling of the arytenoids, and then a larynx and a trachea literally full of typical diphtheritic membrane, the trachea being reduced, as far as I could judge, to about one-third of its normal diameter. The boy returned home and I followed immediately and injected 2000 units of anti-diphtheritic serum. The patient has made a steady recovery and is now practically well. At no time was a trace of membrane visible to ordinary examination. The aphonia was complete for a week, but the voice has now regained considerable volume.

Modbury, Devon.

FOREIGN BODY IN THE EAR.

BY L. K. HENCHEL, M.D. VIENNA.

THE following short account of a case in which a foreign body was impacted in the ear may, I think, be of interest.

The patient was a girl who, when five years old, had a bead of a rosary put into her ear in sport by a playfellow. This fact was kept secret from her parents and teachers (nuns) for two and a half years. After that time the ear was so troublesome that the child was taken to a specialist and then the story came out. The second time this specialist syringed the ear a white bead was found in the basin, but the girl remarked that the rosary from which the bead had become detached was a black one. No attention was paid to this remark at the time. For two and a half years the child suffered more or less from irritation in, discharges from, and pains in, the ear with loss of hearing. The case came to me on Feb. 15th, 1901, with a well-developed furunculosis. As the swelling in the meatus subsided under treatment I saw a black object partially obscuring the membrana tympani, and on syringing with moderate force a shell of japan lacquer came out. The meatus was very much reddened where the foreign body had lain so long—namely, for five years. When the little patient came to me the next day she had a rather severe hæmorrhage from her ear. I could plainly see blood oozing out from the reddened surface. I moistened some pure cotton with liquor ferri sesquichloridi, twisted it firmly over a fine boxwood stick, such as is commonly used on the continent for a toothpick, and under the guidance of the light applied it to the bleeding surface. The further history of the case was quite uneventful. The blood-clot formed by the styptic came away in two portions several days afterwards and the girl, who had been unable to hear a watch quite close to the affected ear, can now hear it as well as with the other ear, and a tuning fork is heard better now with the affected ear than with the other one. Neither the rosary nor the white bead is now to be found, a thing not to be wondered at after a lapse of several years.

OF
HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prœmium.

ST. GEORGE'S HOSPITAL.

TWO CASES OF SARCOMA DERIVED FROM THE PERIRENAL RETRO-PERITONEAL TISSUE ON THE RIGHT SIDE CONTAINING A PSEUDO-CYST.

(Under the care of Dr. H. D. ROLLESTON and Mr. G. R. TURNER.)

THE importance of the subperitoneal tissue as a site for new growths and other morbid processes was not fully recognised before the late Mr. William Anderson's very able paper read at the Carlisle meeting of the British Medical Association. Most of the retro-peritoneal sarcomata grow but slowly; a very good instance of this was reported by Meeringer.[1] Histologically the majority of these growths are spindle-celled sarcomata with a varying amount of fibrous tissue.

CASE 1.—A woman, aged 41 years, was admitted into St. George's Hospital in June, 1899, with the history that she had previously had some signs of more or less intestinal obstruction and was losing flesh. She was a spare woman, with a hard, moveable tumour rather smaller than a cricket-ball in the right iliac and lumbar regions. She had no abdominal distension or signs of intestinal obstruction, but it was thought that she might have malignant disease of the cæcum which did not involve or obstruct the ileo-cæcal valve. After she had been in the hospital for some time she became insane and refused to take her food, so that nasal feeding became necessary. This suggested that there was possibly a secondary tumour in the brain; ophthalmoscopic examination showed that the optic discs were normal. The mental condition continued and, getting weaker, she died.

Necropsy.—At the post-mortem examination, which was performed by Dr. Lazarus-Barlow, the pia-arachnoid of the brain was found to be opaque as in chronic alcoholism, but otherwise the brain presented no gross lesion. In the abdomen a tumour surrounded by a capsule was found lying behind and to the right of the second part of the duodenum and almost in contact with the hilum of the right kidney. The growth had no structural connexion with the kidney, ureter, or suprarenal capsule, all of which were healthy. It was adherent to the right side of the second part of the duodenum. On slitting up the latter a raised crater-like orifice as big as the end of the little finger was found in the lower part of the second portion of the duodenum, well below the opening of the biliary papilla (*vide* Fig. 1). This sinus led into a pseudo-cyst (*vide* Fig. 2) contained in the tumour, evidently produced by breaking down of the white growth. There were no growths elsewhere, and except for a small lipoma attached to the mucous surface of the ileo cæcal valve the other organs were natural. The tumour appeared to have arisen in the retro-peritoneal tissue over the kidney close to the second portion of the duodenum and subsequently to have become adherent to the bowel. It did not appear to have originated in the wall of the duodenum. The tissues round about the tumour were very lax and readily allowed the tumour to move downwards towards the right iliac fossa. This probably accounted for the tumour having during life appeared to be in the region of the cæcum.

Microscopically the growth was a medium-sized spindle-celled sarcoma showing fibrification; in some places smooth muscular fibres with rod-shaped nuclei were present; but the mass of the tumour was undoubtedly sarcomatous. Sections taken from the wall of the pseudo-cyst showed inflammation and necrotic changes.

For the excellent drawings illustrating this case we are indebted to Dr. E. A. Wilson.

CASE 2.—A man, aged 45 years, was admitted into St. George's Hospital with pain in the right hypochondrium which radiated to the shoulders. In the last three months he had lost a stone in weight. There was no history pointing to the likelihood of hydatid infection and syphilis was denied. Two years before he had jaundice and lead colic. He was a thin man with some emphysema of the lungs, but otherwise the thoracic organs were normal. In the abdomen there was a hard tumour continuous with the liver and in the position of the gall-bladder, which bulged into the loin. The surface of the tumour was irregular and a grating sensation suggesting peritoneal friction could be felt over it. There was no thrill or fluctuation. The percussion note over it varied, being sometimes dull and sometimes partially resonant. The urine was natural and there was no jaundice. The diagnosis lay between a renal growth and a tumour growing from the under surface of the right lobe of the liver. He was put on full iodide treatment but without any beneficial result. After he had been under treatment for a fortnight he had pain in the right testicle pointing to some interference with the renal plexus. As the man desired to have something done to relieve his pain Mr. G. R. Turner saw him and agreed to perform an exploratory operation, with a view of, if possible, removing the tumour.

The operation was performed on May 11th, 1900. An incision made in the right linea semilunaris exposed a tumour of the size of a child's head arising from the region of the right kidney and projecting up under and below the right lobe of the liver from which, except for adhesions to the gall-bladder, it was quite free. The tumour had a vascular capsule, but save for its connexions to the back of the abdomen was not united by adhesions to any of the abdominal viscera except the gall-bladder from which it was peeled off. At the back of the abdomen, however, it appeared to be adherent to the inferior vena cava, above, and to the right of, the mesentery. Considering the freedom of the tumour from adhesions and its large size it seemed probable that it might not be a malignant tumour and that its removal, though a formidable task, was justifiable. The capsule contained a number of large veins and bled freely on being incised. Several layers of fibrous tissue were cut through and it was then found possible to peel the capsule off the tumour. The very deep connexions of the tumour to the back of the abdomen made entire removal so dangerous that it seemed safer to remove as much as possible of the tumour piecemeal. This was accordingly done and resulted in the removal of nine ounces of whitish-grey growth closely resembling to the naked eye a fibromyoma of the uterus undergoing early myxomatous degeneration. There was no cavity or pseudo-cyst in the tumour. Some of the tumour together with its capsule was left behind.

Microscopically the tumour was a fibrifying sarcoma composed of medium-sized spindle-cells with oval nuclei. In places there was commencing necrosis of the new growth. A few muscular fibres, with rod-shaped nuclei, probably derived from the subperitoneal tissue where they are normally present, were seen.

A considerable quantity of blood-stained discharge necessitated the dressings being renewed twice in the first 24 hours. Sickness then set in, but was relieved after the plugs of gauze were removed. The patient slowly recovered, and the wound having almost healed he left the hospital, but he returned in August with increase in the size of the tumour and pus discharging from a sinus about the middle of the wound. The patient developed a hectic temperature, had rigors for a week before death, and rapidly went down-hill.

Necropsy.—At the post-mortem examination, which was performed by Dr. O. F. F. Grünbaum, it was found that there was a large white tumour adherent to the scar, the under surface of the right lobe of the liver, and the small intestines. It arose from the retro peritoneal tissues over the right kidney, and though readily separated was adherent to the outside of the capsule of the kidney in its anterior third. The right suprarenal body was healthy and independent of the growth. The growth, which was lobulated and of the size of a man's head, contained a central cavity filled with about three-quarters of a pint of dark brown very offensive fluid—sanious pus. There were no secondary growths in the body.

Microscopically, the growth was adherent by its capsule to the surface of the liver; but there was no invasion of the liver by new growth. The tumour had evidently contracted

inflammatory adhesions as the result of the operation to the neighbouring parts, and had softened down in the centre into a pseudo-cyst. In other respects it was much the same as at the operation. Microscopically, it was a medium-sized spindle-celled sarcoma *As in the growth removed at the* operation there were areas where the growth was fibrifying. Examination of the walls of the pseudo-cyst showed necrotic changes and infiltration with red and white blood corpuscles.

Remarks by Dr. ROLLESTON *and* Mr TURNER —The points of interest are as follows. 1. The occurrence of encapsuled sarcomata arising from the retro-peritoneal tissue over the right kidney. Retro peritoneal sarcomata are uncommon; Gurlt found that in 14 630 tumours examined at Vienna, of which 894 were sarcomata, there was only one from the retro-peritoneal space. In an analysis of 61 recorded examples tabulated by Dutton Steele[1] it appears that the right side of the body is more often affected, but no explanation for this is forthcoming. 2 Though histologically sarcomatous, parts of both tumours presented an appearance which might be taken to suggest that a fibromyoma had become transformed into a sarcoma That this was the case in this instance we do not believe; it is more probable that the smooth muscular fibres were included in the growth and were those found in the retro-peritoneal space. Smooth muscular fibres were present in two retro-peritoneal sarcomata collected by Steele. It may, however, be pointed out that retro peritoneal leiomyofibromata have been described[2] and that uterine fibromyomata may undergo sarcomatous change[3] 3. The freely moveable condition of the tumours (in Case 1 at the necropsy and in Case 2 at the operation), their encapsulation, the general absence of infiltration, and the fact that there were no secondary growths show that in spite of their sarcomatous structure the growths were comparatively benign. 4. The formation of pseudo-cysts in the centre of both these tumours. This would appear to be fairly common in tumours derived from the retro-peritoneal space; in his 61 cases Steele found this change in 35 per cent It is probable that in our cases the cyst formation was due to inflammatory and necrotic changes set up by infection, in Case 1 from the duodenum and in Case 2 from the operation wound. 5. The great difficulties that may arise in the complete removal of growths derived from the retro-peritoneal space, even when, as in our cases, the tumours are more or less pedunculated. In Case 2 the growth was adherent to the inferior vena cava and so could not be entirely removed, while in Case 1 the duodenum would have to have been opened had removal been undertaken. In other cases of retro peritoneal sarcomata that we have seen the growth has been flattened and spread out behind the peritoneum, and operation, which was not suggested, would, if attempted, have been quite futile.

HEALTH MATTERS IN POPLAR.—The energetic medical officer of health of the borough of Poplar Mr. F. W. Alexander, has recently issued a circular to the owners and occupiers of wharves, factories, and workshops dealing with the question of rats and the plague. He asks that if any unusual mortality is detected among rats he should immediately be informed of the same. He also gives notice that arrangements have been made with Dr. E. Klein for the bacteriological *examination of the body of* any rat which it is thought desirable should be examined Mr. Alexander has also made a report to the Housing Committee of the borough which embodies various opinions and suggestions already made as to the best manner of carrying through a reform in the all-important question of the housing of the poor. Besides these opinions Mr. Alexander adds some suggestions of his own which are eminently practical. The sanitary authority has also issued some admirable hints regarding the management of infants, drawn up by their medical officer of health for gratuitous distribution. The appalling manner in which the children of the poor are fed is only too well known to every hospital physician and so far as instructions go those of Mr. Alexander are admirable, but poverty, laziness, and, we must add, the despair born of the perpetual struggle for bread and money for the rent go far to do away with the effect of any instruction.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A CLINICAL meeting of this society was held on April 26th, Sir R. DOUGLAS POWELL, the President, being in the chair.

Sir HUGH BEEVOR exhibited two Healthy Left-handed Adults to illustrate the normal thoracic resonance in left-handed persons. They afforded positive proof that the lesser resonance of the right chest in right-handed persons was due to the greater muscular development on that side. He remarked that in the absence of emphasis upon this point in text-books mistakes were still often made and disease was wrongly suspected. Dr. W. H. Brazil[1] had emphatically called attention to this point in left-handed persons It might be noted in these cases that the pulmonary resonance did not rise so high above the left clavicle as above the right The diminished resonance, or higher note, could be detected below the clavicle quite distinctly in the younger man He had found no reason to suspect that either patient was the subject of disease. These observations were repetitions of others which he had made formerly upon left-handed persons —The PRESIDENT asked Sir Hugh Beevor whether he had invariably noticed that in right-handed persons the percussion resonance extended higher on the right than on the left side.—Dr. PERCY KIDD asked whether the normal defective *resonance was chiefly in the apical region or whether it was* universal.—Sir HUGH BEEVOR in reply, said that he had not found the difference on the two sides an invariable rule, but it was a common occurrence. It was his practice to carry the resonance up above the clavicle as high as possible, and it did not generally extend as high on the right as on the left whereas in these left-handed persons it extended highest on the right

Dr. F. G. STILL exhibited a case of Unusual Obesity *in a Child aged seven* and a half years, who weighed 4 stones 11½ pounds and measured only 42½ inches in height. He was very thin a year ago, when he became rapidly fatter; since that time there had been a steady increase of fat, and during the last two months he had been somewhat short of breath. Within the last three weeks the lower part of the abdomen and the upper parts of the thighs had shown irregular bluish-red lines, where the skin was thinned and shiny with dilated venules, evidently analogous to "lineæ gravidarum" A month ago he awoke one morning quite blind, but otherwise in his usual health; the blindness lasted 48 hours. Sight was normal when the child awoke on the third morning. He *complained occasionally of some pain "like pins and* needles" over the vertex of the head, but otherwise there had been no pain anywhere. At the age of three and a quarter years the child had some severe illness which began with *convulsions and was called ' peritonitis." It lasted four* months and since then the abdomen had always been rather large With the exception of an attack of measles at the age of four years the child had had no other illness. One brother had had pulmonary tuberculosis, and there was some more distant history of tuberculosis The other members of the family were all thin There was some hair over the pubes, which was said to have been present for two years; the child's voice was not gruff. The right testicle was *normal; the left* was not felt. The thyroid gland could not be felt; it was certainly not enlarged. The viscera seemed to be normal. The heart showed nothing abnormal except an occasional slight irregularity of rhythm and marked accentuation of the second sound in the aortic area.—Dr NORMAN DALTON remarked that this case, excepting in point of age, resembled one which he had seen last year. The patient was a woman aged 30 years, who in the course of a few months had developed obesity, a growth of hair on the face, a dark complexion with certain symptoms of Graves's disease—viz, thyroid enlargement and tachycardia The child in Dr Still's case had a rapid pulse. His (Dr. Dalton's) patient had rapidly entered the typhoid state and had died. He believed that the two cases resembled each other.—Sir DYCE DUCKWORTH had met with sporadic instances of obesity in gouty families. He could not explain the connexion, but it was an undoubted fact, and some French observers had recognised the association and had named the condition "arthritic obesity."—Dr. Still, in reply, remarked that in view of the pubic and facial hair he could not help thinking that the obesity was in some way connected with premature puberty and he referred to the case of a child, aged 13 years, who was enormously fat and who had begun to menstruate at the age of 10 years. The obesity of eunuchs probably had some explanation of the same kind. The sudden loss of vision in the case he had brought forward was, he suggested, possibly a neuropathic change. He had recently had a case of "lipomatosis neurotica" under his care; perhaps this case was of a neuropathic order.

---

[1] Brit. Med. Jour, Oct. 28th, 1899

Sir Dyce Duckworth exhibited a case of Myxœdema which had been under observation at intervals for 23 years. The patient began to manifest symptoms of myxœdema in 1878, and she came under his care as an out-patient at St. Bartholomew's Hospital in 1879. He recorded the particulars of her case in the Transactions of the Clinical Society of London for that year. He lost sight of her for some time, but she subsequently came under his care in 1893, weighing 14 stones 4 pounds, and she remained for three months under observation. Her weight was reduced to 10 stones 5½ pounds. Her case was one of the earliest which had been brought before the notice of the Clinical Society of London, and at that time the precise nature of the malady was not ascertained. The influence of thyroid treatment was most marked in this instance. The patient was growing steadily worse and was becoming languid, helpless, and lethargic—a burden to herself and to her family. Within a few months she regained her juvenile figure and became bright and useful once more. Her present complaint was chiefly of headache and there was no obvious relapse of the myxœdematous state. She had taken thyroid elixir (one fluid ounce, equal to one thyroid gland [sheep's]) in fluid half-ounce doses per diem for long periods, then less and less to the amount of two fluid drachms in a week for years. Her present weight was 10 stones 13 pounds. There were no supraclavicular fatty masses to be felt.—Sir Dyce Duckworth, in reply to Dr. Alexander Morison, said that the patient's pulse had always been slow. This case was one of the earliest that had been brought before the society, in 1880, when the disease in this patient had already existed some time. Every time she took the thyroid elixir the improvement had been immediate and marked. She was at one time nearly bald, but her hair had grown again, and she now looked remarkably young for her age. She had borne four children since commencing treatment, the first one being rachitic.

Dr. C. E. Beevor exhibited a case of Retro-colic Spasm occurring in a man, aged 44 years. For five years he had had occasional attacks of muscular rheumatism in the lumbar region. The present illness had begun two years before with "lumbago"—i.e., sharp pains in the back—which became later of a dull, aching character. In 1899 he had spasm of the muscles round the hip, with hardness and stiffness there, which gradually passed up to his shoulders, and by September, 1900, he had marked retention of the head and the neck. As the patient lay resting at full length there was no spasm, but on sitting up, and especially on walking, he got spasm of the muscles of the neck so that the cervical spine was extended with the concavity backwards and the chin was depressed. The extensors of the head, the complexus and trapezius, did not contract and the muscles affected were probably the deep extensors of the cervical spine. The
no-mastoids were tightened up, but apparently they were
pasmodically contracted. On walking the erector spinæ
ted spasmodically, producing lordosis and throwing
t forwards. The spasm ceased if the head was
fall forwards fully flexed, or if any support was
e head from behind, or on lying down. The
nsisted of the "Weir-Mitchell," suspension
hree times a day for 90 seconds, strychnine,
bromides, belladonna, and the constant

ON exhibited a case of Lymphadenoma
ths in the Skin. The patient was an
rs of age, who presented numerous
Pseudo-cyst in the sarcoma ope. different parts of the body, and
com he chest and elsewhere. He had
lministration of arsenic, during which time he had become worse and the lymphoid growths had developed in the skin. Since the cessation of the arsenic there had been diminution of the lymphoid growths and general improvement had taken place.—Mr. W. G. Spencer remarked that there were several features which suggested a mixed infection of tubercle and inherited syphilis in this case. The glands in the neck were, he believed, tuberculous; the nodule on the tibia and the pigmented scars were syphilitic.—Dr. A. E. T. Longhurst quite agreed with the last speaker and thought that anti-syphilitic treatment should be tried.—Sir Hugh Beevor had recently had a case under his care which had been diagnosed to be lymphadenoma, but at the necropsy it turned out to be tuberculosis.—Dr. Percy Kidd asked if the blood had been examined.—Mr. Charters Symonds suggested that a microscopical examination of the lesions might throw light on the case.—Dr. Lee Dickinson, in reply, could not regard the case as one of mixed infection. Almost every gland in the body had been affected at one time or another. Excepting the node on the tibia there were no signs of syphilis. He had examined the blood on two occasions; the red corpuscles were diminished, the white corpuscles were about twice the normal. The patient had had arsenic continuously for eight months, but had got steadily worse; during the last six months without it he had improved.—Dr. A. G. Phear recalled certain cases of syphilis now under his care. When arsenic was given to these patients infiltrations arose in the skin which went on to ulceration. On ceasing the arsenic the masses disappeared. He was afraid that microscopical examination of the case under discussion would not help them very much, for no line could be drawn between the structure of lymphadenoma and gumma of the skin; both were granulomatous material. He believed that this case was syphilitic.—The President suggested that Dr. Dickinson would perhaps report later the results of anti-syphilitic treatment.

Dr. Percy Kidd exhibited a case of Congenital Heart Disease (? Patent Ductus Arteriosus). The patient was a woman, aged 21 years. She exhibited slight cyanosis, especially of the conjunctiva, but no clubbing of the fingers. The heart was enlarged on the right and the left sides; a faint diastolic thrill could be felt in the second left space; the second sound everywhere was very loud, with the maximum intensity at the third left cartilage. At this point a short diastolic murmur following the second sound was audible at times. The first sound was everywhere feeble and generally doubled. The patient had suffered from attacks of cardiac pain from childhood and from dyspnœa for three years. There was no history of rheumatism, scarlet fever, or chorea.—Dr. W. Forbes Ross asked if it was possible to exclude aortic regurgitation from this case. An aortic regurgitation murmur could be heard as loudly on the left as on the right of the sternum, a fact which he believed Dr. Ringer was the first to point out. The facts of this case would fit in with that diagnosis.—Dr. Seymour Taylor pointed out that the characteristic pallor of aortic regurgitation was wanting in this patient, but on the other hand she presented cyanosis.—Dr. Parkes Weber asked if Dr. Kidd had considered the possibility of tricuspid stenosis.—Sir Dyce Duckworth was inclined to agree with Dr. Kidd's diagnosis. During life the diagnosis of these cases was largely a matter of guesswork.—Dr. Alexander Morison thought that the diagnosis "patent ductus arteriosus" was properly marked with a query. Pulmonary regurgitation might exist without any symptoms whatever. He would suggest as a possible diagnosis that it might be one of those rare cases of slight mitral stenosis, probably congenital.—The President remarked that this was an interesting and obscure case about which many diverse opinions might be expressed. He did not agree that the diagnosis of mitral stenosis was out of court. In point of fact, there were two important clinical evidences of stress in the pulmonary circulation—viz., marked hypertrophy of the right ventricle and a strongly accentuated second (pulmonary) sound. In his opinion the first part of the doubled first sound might be regarded as a prefix. The heavy and palpably thudding second pulmonary arterial sound was certainly prolonged. It might be that the valve had become strained. He would not, however, venture to express a more decided opinion and he hoped that Dr. Kidd would keep the case under observation and would report again about it.—Dr. Kidd, in reply, could not admit the possibility of aortic regurgitation. He, like many of those who had spoken, had thought that the disease was mitral stenosis when he first saw the patient. But on further investigation he thought patent ductus arteriosus was more probable. It was, however, only possible to hazard an opinion on these cases during life

Dr. PERCY KIDD also exhibited a case of Myxœdema in a girl, aged 14 years She presented on admission, in February, 1901, the typical appearances of that disease and the thyroid gland could only be felt with difficulty. There were firm, fatty masses in both supra clavicular fossæ The expression was stolid, but the intelligence was good. When she left school, at the age of 13 years, she had reached the fourth standard. The history suggested a congenital origin, though the appearances were not those of cretinism. The child did not walk till the age of two and a half years, and she used to pass urine and stools in bed up to the age of six years At two years old she began to get very fat She had always been sluggish and not nearly as bright as the other children. For the last 12 months she had suffered from increasing hebetude and frequent headaches Treatment with thyroid extract produced rapid improvement, and the appearance of the child was no longer characteristic of myxœdema — Dr SEYMOUR TAYLOR took exception to the term "myxœdema" being applied to this case. He thought that it was rather a mild degree of cretinism Up to the age of two years the child could not walk and passed her evacuations under her Sir William Gull's definition of myxœdema was "a cretinoid condition supervening in adult women" Moreover, he would like to ask whether the word "myxœdema" should not be done away with altogether. An excess of mucin was not really found in the tissues, as originally thought, and the word "myxœdema" had therefore no real meaning —Dr. KIDD, in reply, admitted that the child was backward The case was interesting, as showing the connexion between myxœdema and cretinism

Dr FRANCIS WARNER (introduced by Dr PERCY KIDD) exhibited a case of Hypertrophic "Pulmonary" Arthropathy occurring in a woman, aged 36 years She had had influenza 18 months ago. 12 months ago the fingers gradually began to swell, commencing with clubbing of the tips; the knees also began to swell, and the feet and ankles All the affected parts had got much worse lately. She had had pain which became worse after exertion in all these affected parts The features were not altered She had wasted generally and had lost 4 stones 4 pounds in weight She had had cough this past winter, but previously she had not been subject to any lung troubles The nails were large and curved There was considerable thickening round the phalangeal joints; the metacarpus and metatarsus were thickened and there was thickening of the lower third of the shafts of the legs and of the bones of the forearms There was some effusion into the wrists and knees, especially into the latter. There was wasting of the spinal muscles and interossei and of the small muscles of the hands. The face was not affected —Mr. RAYMOND JOHNSON asked if there were now, or if there had been at any time, physical signs in the lungs If not what was the reason that the term "pulmonary" had been applied? He suggested a possible septic source for the joint mischief, and asked if the patient had had leucorrhœa —Dr. W FORBES ROSS had elicited a history of "hysterical" fits or attacks in this patient He had had nine patients under his own care with epilepsy with the same joint mischief. Might not the joint trouble in Dr. Warner's case be of nervous origin?—Dr. C E BEEVOR pointed to the hands, which were large and sausage-like, and suggested acromegaly, but there were none of the other symptoms of that malady Had this been thought of?—Dr. WARNER, in reply, said that there were no signs, nor was there any history, of lung trouble The case, however, fitted in with Marie's description of pulmonary osteo arthropathy In 10 out of that observer's 95 cases there were no evidences, nor was there any history, of lung disease There were no evidences of nerve origin in this case, nor were there other symptoms pointing to acromegaly. Moreover, in acromegaly the enlargements affected the ends of the bones; whereas here the increase was all along the shafts Radiograms from the case were exhibited demonstrating these features in the two diseases

Mr. J. HUTCHINSON, jun, exhibited a case of Inveterate Ulcer of the Hand occurring in a man, aged 36 years. In April, 1900, he noticed a small red spot on the dorsum of the right hand, which ulcerated and spread, only healing up slightly at the original starting-point. He was under treatment for struma for four months without improvement The ulcer was then scraped at the Royal Free Hospital without result He was treated at the London Hospital by Roentgen rays and iodides internally from September, 1900, to March, 1901, with some temporary improvement He was transferred to Mr. Hutchinson's care on March 27th, 1901, and was now being treated with mercurial ointment and the ulcer was slowly healing —Mr CAMPBELL WILLIAMS could not regard this case as any form of scrofuloderma The mischief, whatever it was, had started from a small scratch, and the case, both in its history and its present features, was highly suggestive of that rare condition, dermatitis repens. He could call to mind a case resembling this one in which the process went on for nearly a year, but when properly treated it got quite well.—Mr HUTCHINSON, jun, in reply, was inclined to regard this case as one of strumous ulceration occurring in skin which was badly nourished The process was allied to Bazin's disease and, like that malady, it was healing with remarkable rapidity by the simple means of keeping the part warm

Mr. CHARTERS SYMONDS exhibited a case of Dislocation of the Patella occurring in a young man. The condition was probably congenital, though the history was somewhat indefinite.

Mr. CHARTERS SYMONDS also exhibited a case of Hæmorrhagic Gummatous Myositis occurring in a man, aged 45 years. There was a hard, irregular, infiltrating mass in the extensors of the right thigh, over which the skin presented an infiltrating eruption. — Mr. CAMPBELL WILLIAMS asked if this case might not be true sarcoma of the muscle It came on so very quickly after injury.—Mr. CHARTERS SYMONDS replied that when the patient came under treatment a year ago (one year after the injury) the swelling was larger than it was now, and he thought that this was rather against the diagnosis of sarcoma

Mr. CHARTERS SYMONDS also exhibited a girl whose Knee-joint had been Erased eight years before The case was exhibited to show the condition of the knee joint The movement was free to a right angle, but there was a good deal of weakness The question raised by the case was whether the patient was as well off as she would have been after excision He (Mr Charters Symonds) suggested that a stiff leg would probably be more useful than was the present condition —Mr W G SPENCER referred to a similar case shown by Mr Ede in which movement of the joint was obtained —Mr RAYMOND JOHNSON asked what steps Mr Charters Symonds took to obtain fixity He (Mr. Johnson) was not sure if this patient was a gainer by having a moveable joint —Mr CHARTER SYMONDS said that he had exhibited the case because he thought it was instructive as to the result At the operation everything was taken away excepting a portion of the cartilage covering the ends of the bones He remembered Mr. Ede's case; it was shown as the most desirable result that could be obtained and the amount of movement which was possible was not quite up to a right angle He thought, on the whole, that they had better fix these joints

BRITISH GYNÆCOLOGICAL SOCIETY.

Retroversion of the Uterus.

A MEETING of this society was held on April 25th, Dr. J. A. MANSELL MOULLIN, the President, being in the chair.

Dr. H MACNAUGHTON JONES introduced the discussion on Retroversion of the Uterus and backward displacements generally by a review of the anatomico physiological points bearing on their etiology He accepted Schultze's definition of retroversion, drawing the distinction between retropositions and deviations and retroversion or retroflexion, briefly touching on such causes as atonicity in the abdominal parietes, over-distension of the bladder, rectal complications and neglect of constipation, perimetritis with exudations or adhesions, pregnancy or the puerperium, subinvolution, tumours of the uterus, in the broad ligaments, or bladder. He noticed the causal relationships between ovarian growths and retroversion In the uterus itself metritis, tumours, and congenital conditions were referred to and the mode of action of these various causes in altering the normal axis of the uterus was touched on, as well as the supports of the uterus in altering its axis directly or indirectly. The relation of perineal and vaginal abnormalities was considered and the clinical division of backward displacements into those in which the uterus was reducible and moveable, with or without complications, and those in which the uterus was adherent and irreducible, with or without adnexal complications, was accepted for its practical value in determining the treatment. The importance of the dorsal position and the combined methods of examination, as well as the knee-elbow, in diagnosis, as also the advantages of Schultze's directions for diagnosis and manipulation, were noticed. Having touched on the various symptoms arising from retroflexion he said that from every point of view he refused to count a woman as healthy who had a retroverted uterus, this not only from its physical causes, but from its psychical effects. Reviewing the prophylactic treatment, the importance of attention to the bladder under ordinary conditions, when wearing a support and after labour, attention to the rectum, and the position of the uterus during the puerperium, as well as the need for following up the convalescence after pelvic inflammations generally by securing complete resolution of all effusions and the normal position of the uterus, were dwelt on, as also the means to be taken to absorb plastic exudations and correct peritoneal contractions. Attention to such clinical points would render retroversion a matter of much less frequent occurrence than it was at present, the wider recognition of the causes leading to its earlier rectification effecting more rapid and permanent cure. Dr Macnaughton-Jones placed three propositions before the meeting: 1. Every mobile and reducible uterus should always be treated in the first instance by a support, worn for a space of time proportionate to the tendency there was on the part of the uterus to revert to the backward position. Associated adnexal conditions were frequently amenable to treatment in such cases, and it should precede and follow the reposition of the uterus. 2. Should the adnexal condition be such in this class of case as to demand operation, colpotomy was that of selection, with resection of the adnexa and the subsequent use of a support. 3. An immoveable or irreducible uterus, or a reducible uterus in which the associated conditions in the uterus itself, in contracted peritoneal folds, or adnexal adhesions, made it clear that no pessary would effect a cure or enable the uterus even temporarily to remain in the normal position, should be treated by operation, the nature of which would depend on the age and child-bearing prospects of the woman, the amount of adnexal disease, the condition of the vaginal outlet and perineum, such complications as cystocele or rectocele, and the coexistence of uterine disease with the displacement Dr. Macnaughton-Jones entered into an analysis of the cases in which a pessary, with collateral treatment, should be the plan of treatment adopted and also of those in which operative measures were absolutely necessary. The views of Delajaniérè, Goldspohn, Kohn, Veit, Rissman, and Flaischlen were specially referred to, and the various operative procedures following on Alexander's method or modifications of it, as those of Kustner, Edenbohls, and others, formed the first class of operative interferences. In the second were the extra-peritoneal or intra-peritoneal fixation of the uterus itself to the vagina, as in the operations of Müller, Duhrssen, and A. Martin; and in the third class of fixation of the uterus by the direct mesial methods, as in the operations of Leopold, Czerny, Pozzi, and others, the lateral of Olshausen and Sänger, or the suspension method of Howard Kelly (fixation to the peritoneum and sub-peritoneal fascia). The operation he himself performed was either ventro-fixation or suspension, and where he considered it necessary to operate he thought cœliotomy afforded the best and safest means of correcting the majority of adnexal complications with no greater danger to pregnancy than by other methods. Given a simple case of mobile and reducible uterus it now appeared from the mass of evidence before the profession that the Alexander-Adams operation was the classical method of dealing with such a condition.

Dr. W. ALEXANDER enumerated many clinical consequences which he had proved again and again to be the result of backward displacement. When the displacement was acute and recent the symptoms were prominent. As the disease became chronic the symptoms disappeared and this fact gave rise to the statement that the displacement had no symptoms. What would be said of a surgeon who, finding an old mobile dislocation of the shoulder, said that a recent dislocation produced no symptoms; yet the cases were parallel. Displacements resulted from sudden strain or wrench or over exertion at the menstrual period, and occurred in connexion with miscarriage, abortion, and confinement. By palliative treatment the symptoms might be entirely relieved. It was only a question of time, care, and skill, but often these were unavailable, and operative treatment was generally necessary. Referring to his own operation, shortening of the round ligaments, if the uterus sloped back ever so little it would prove a failure and he thought that this was the source of failure in a good many cases. Where adhesions were present he opened Douglas's pouch, passed in his finger and broke them down, until the uterus could be easily pushed forward into anteversion. He then shortened the round ligaments, having packed the vagina with gauze. If any lesion were found in the pelvis he removed it by the vaginal opening at the same sitting.

Professor J. W. TAYLOR said that backward displacement was a dislocation which, when recently acquired, often occasioned great suffering, especially if associated with metritis and menorrhagia, but which when chronic and not accompanied by enlargement of the uterus might not give rise to symptoms. It was therefore the recent or the intractable cases, in which the uterus was enlarged, which mainly required treatment, and this to be successful should deal with the enlargement as well as the displacement. Treatment by pessary was rarely curative, though valuable in relieving urgent symptoms and in enabling the surgeon to estimate how far symptoms were due to the displacement. He had considerable operative experience of vagino-fixation, though in most cases it had been simply incidental to anterior vaginal cœliotomy, and also of ventro-fixation, though it had generally been accessory to other operations involving abdominal section. In vagino-fixation, if the union were sero-serous only, it sometimes gave way. He had had two such cases. If the union were firmer there was undoubted danger in subsequent pregnancy. Illustrative cases were quoted. The older operation of ventro fixation rarely gave the patient a feeling of perfect relief and security. He had performed Kelly's operation as accessory to other abdominal operations and had been very pleased with the results. Doyen's operation he found to be insufficient. Doyen himself now combined it with shortening of the round ligaments. Shortening of the round ligaments, or Alexander's operation, he believed to be far and away the best for uncomplicated cases of backward displacement. When, as in most cases requiring operation, chronic endometritis was present he began the round ligament operation by vaginal disinfection and curetting.

Dr. C. ROUTH believed that there were many cases of retroflexion which would yield to treatment with a stem pessary if associated with other measures, which would prove intractable, whatever mode of treatment were adopted, if a stem pessary were not employed. Hæmorrhage, which was usually considered an objection to the use of the stem, he regarded as beneficial, inasmuch as it relieved uterine congestion.

Mr. F. BOWREMAN JESSETT said that where there was no doubt as to the diagnosis or as to whether the fundus was fixed by adhesions he had the patient anæsthetised. Under an anæsthetic it was often found that a uterus which had previously appeared to be absolutely fixed could be readily replaced in the normal position. A large number of patients could be relieved and cured by the introduction of a pessary. He employed a Hodge with a large glycerine pad for two or three months when he replaced it by an ordinary Hodge or Smith-Hodge. Stem pessaries were sometimes of much service if introduced for a week, the patient being kept in the recumbent posture. If an operation was necessary he preferred ventro-fixation.

Dr. GEORGE ELDER agreed with Dr. Alexander that the chief causes of retroversion and retroflexion were excessive exercise at the menstrual periods and badly attended miscarriages and confinements. He now and then used a stem in combination with a pessary and believed that it assisted drainage and relieved congestion. With regard to treatment in unmarried girls, a properly fitting Hodge, supplemented by general treatment, was sufficient in most cases. If a uterus was found to be enlarged and retroverted or retroflexed directly after labour or miscarriage steps should be taken to bring about involution. After the acute stage had passed care should be taken that any metritis present was treated and the perineum, if ruptured, should be repaired before applying the pessary. The difficulty he experienced in finding the round ligament had led him to abandon Alexander's operation and he now performed abdominal ventro-fixation.

Professor JAPP SINCLAIR did not think that it was a justifiable proceeding to leave the uterine stem in longer than a fraction of a week. In his opinion Alexander's operation, which he had performed 40 or 50 times, was only suitable to cases in which no complications existed—that was to say, cases which could be cured without operation. If from the condition of the uterus the retroflexion had obviously existed for some time, and the case could not be cured without operation, the only safe procedure was ventrofixation. Essential points were, if a subsequent pregnancy were probable, that the fundus uteri be not involved in the stitches and that the physiological play of the round ligaments be preserved.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 19th, Dr. Gordon Black, the President, being in the chair.—Dr. Gordon Sharp read a paper on *Food and Disease* in which he asked the members of the profession not only to take a greater interest in this important question but also to study the subject in a more comprehensive fashion and in the light of common sense so that the medical profession might be, as it ought to be, the only dictator in all matters relating to food and disease. In the treatment of Bright's disease and diabetes mellitus he advocated not so much an abstinence from proteids and carbohydrates respectively as a dietary that would maintain the balance of health. Science did not teach that they were to give no proteid in Bright's disease or no carbohydrates in diabetes She only taught that the equilibrium would be more easily upset by proteids in Bright's disease and by carbohydrates in diabetes than by other food. In the treatment of dyspepsia Dr. Sharp pointed out the danger of loading the alimentary tract with brown bread, farinaceous food, and cocoa, and he advocated the judicious employment of meat and said that cocoa was not a good food in dyspepsia because it was flavourless and insipid, while tea when rightly prepared had a delicate aroma and answered well. He spoke of the danger attending the use of dried proteids and tinned foods on account of the lack of natural flavour and zest. In the feeding of infants he was inclined to employ unboiled milk and risk tuberculosis rather than to run the more frequent risk of malnutrition due to the use of boiled milk. He believed that the loss of citric acid in boiled or pasteurised milk was not, as had been asserted, the cause of malnutrition and infantile scurvy, the disproof being that scurvy could be cured or prevented by eating potatoes or other fresh vegetable which contained no citric acid or allied body Boiling or pasteurising altered not only the composition but also the constitution of the milk, and if it had to be put in one sentence he would say that the malnutrition depended on a loss of freshness in the milk. However, the most important factors were loss of flavour, loss of salts in general, and loss of gaseous bodies —The President, Dr. T. Churton, and Dr. R. H. Crowley discussed the subject and Dr. Sharp replied.—Dr. A. Bronner (Bradford) read a paper on Headaches of Nasal Origin. He regretted the fact that nasal surgery had been under a cloud for the last few years Some physicians even went so far as to declare that asthma *could never* be caused by nasal disease. This was going rather too far. There was nothing very characteristic or typical about headaches of nasal origin. Nasal obstruction or hypertrophic rhinitis generally gave rise to dull, aching pain with all the symptoms of so-called "aprosexia" Disease of the nasal accessory cavities generally gave rise to local neuralgic pain, often intermittent and worse in the morning. Empyema of the maxillary antrum often caused severe frontal pain, so that in many cases disease of the frontal sinus was wrongly diagnosed Diseases of the sphenoidal sinus was generally accompanied by severe pains behind the eyes and incapacity for any mental or physical exertion. Empyema of the ethmoidal cells was the commonest cause of recurrent nasal polypi The pains in the head varied according to the position of the cells affected. Dr. Bronner briefly recorded the history of several typical cases. Diseases of the nose and accessory cavities were extremely common in Yorkshire and were generally not diagnosed or treated. In all cases of headache the cause of which could not be discovered and in which any nasal symptoms were present (nasal obstruction, discharge, sneezing, &c) the nose should be carefully examined and, if necessary treated. If this were done they should not so frequently hear of the so-called incurable or "nervous headaches."—The President, Dr. T. W. Griffith, Dr Churton, Mr. T. Pridgin Teale, Dr. James Kerr, and Mr. G. Constable Hayes took part in the discussion and Dr. Bronner replied —The following cases and specimens were shown: Mr. Secker Walker: (1) A case of Mastoid Suppuration accompanied by Lateral Sinus Thrombosis, Necrosis of the Cochlea and Post-pharyngeal Abscess; (2) two cases of Chronic Otorrhœa cured by the Mastoid Operation; and (3) a case of Opaque Optic Nerve-Fibres.—Mr. Walter Thompson: A Fibroid of the Broad Ligament.—Dr. E F. Trevelyan: A Dura Mater Showing the Formation of a False Membrane.—Mr. B G. A Moynihan: (1) A case of Tuberculous Ulceration of the Tongue; (2) a case of Choledocho-Duodenostomy; (3) a Stomach showing two Perforating Ulcers, one on the anterior and one on the posterior surface; and (4) a Calculus formed round a Foreign Body in the Prostate Gland —Mr H J Roper: Fœtus and Secundines which were retained in the uterus for 12 months.—Mr. Edward Ward: (1) *Recurrent Sarcoma of the Lower Jaws; extensive excision* (patient and specimen); and (2) an Enlarged Thyroid.—Dr. J. B. Hellier: (1) A Uterus removed by Abdominal Hysterectomy for unusual condition; (2) Fœtus which was delivered by Decapitation; and (3) (for Mr. W. H. Drury of Otley) a Five Months' Fœtus in membranes showing the relations of the chorion, amnion, and placenta —Mr. Lawford Knaggs: A Calcified Fibroid Tumour of the Uterus —Dr. C. M. Chadwick · A Perforated Gastric Ulcer.—Mr. W. H. Brown: A Perforated Gastric Ulcer in an Hour-glass Stomach.—Dr W H. M. Telling: (1) An Aneurysm of the Apex of the Heart, and (2) Rupture of a Blood Cyst of the Left Ventricle.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY—A meeting of this society was held at 20, Hanover square, W, on April 17th, Dr. Frederic Bagshawe (St. Leonards), the President, being in the chair.—Dr. Symes Thompson read a paper on the Climate of Algiers. He showed that Algiers was now easily reached from London in two days and that it was warmer and more sunny than was the Riviera The combined influence of the ocean and the deserts gave to the climate a value which deserved fuller recognition. Whilst Algeria itself was humid and sometimes relaxing, the hills around were exhilarating and at Hammam R'irha, 60 miles to the west and 2000 feet above sea-level, a valuable spa was available in winter when European spas were closed. At Biskra, 200 miles inland, a desert station was reached by railway having a spring as valuable as that of Aix-la-Chapelle, especially in chronic syphilitic cases, whilst at Hammam Meskoutine the boiling spring issued forth in the middle of beautiful country and supplied a haven of rest from the bustle and turmoil of towns.—The President alluded to the account given by Dr. Henry Bennet of his experience of Algiers some 40 years ago, when he described the exposure of the place to cold northerly winds in contrast to the protection of the Riviera from similar winds The further development of the town had no doubt enabled them to select more favoured positions for their modern buildings. Dr. Thompson's account of Biskra and other spas available for sulphur bath treatment during the winter months were instructive and would prove valuable.—Dr. Fortescue Fox commented upon the paucity of stations suitable for spa treatment during the winter months. The mineral waters of North Africa were chiefly of value for winter treatment.—Dr. Douglas Kerr (Bath) said that having visited Algiers personally in 1879 he was much struck with the great advance in comfort and suitability for invalid visitors He also recognised the advantage for syphilitic patients taking mercurial treatment in winter and also the greater privacy.—Dr. Parkes Weber asked for further information as to shelter from winds at Biskra —Dr Thompson, in his reply, admitted that Biskra was 500 miles further north and that it was colder and probably somewhat more windy than Helouan —Mr A G S Mahomed read a paper entitled "Polypharmacy in Nature and Art." He first endeavoured to defend the principle of polypharmacy in art To do this he had prepared tables giving the hypothetical therapeutic equivalents of a group of drugs He showed by examples from this the possible advantages of combining them with a view to resultants in a given direction. Observing that this was the only justifiable polypharmacy he defined what was unjustifiable Turning to nature he pointed out that in most mineral waters there were six or seven elements; of these potash and soda were partly antagonistic; lime and magnesia appeared almost wholly so. In vegetable drugs opium, bark, ergot, calabar bean, and digitalis contained opposing elements. He deprecated the exclusive use of alkaloids, preferring in many cases to use an extract of bark to quinine or a liquid form of opium to morphine.—Dr. Thompson, who supported Mr. Mahomed in maintaining the greater value of the crude drug over its separated alkaloids, said that every effort made to distinguish with precision the value of each constituent of a prescription deserved encouragement.—The President thought that Mr. Mahomed's attempt to estimate the value of various drugs by an arithmetical method might not be concurred in by other prescribers. Every man formed his own relative estimate of the exact value of a drug and would use drugs in accordance with that estimate. Mr. Mahomed's attempt would make men more thoughtful in the employment of remedies.—Dr. E. G. Gilbert (Tunbridge Wells) suggested that Mr. Mahomed's paper and interesting little tables would have been still more interesting if he had stated how he arrived at the exact, or even approximate, percentage of effect produced in one direction and another by each of the drugs mentioned, particularly with regard to the diaphoretics and diuretics. He (Dr. Gilbert) had watched scores of times for their effects upon the skin and kidneys and had nevertheless failed to perceive that they had any decisive action. Mr. Mahomed's estimate that potassium acetate was more diaphoretic and less diuretic than ammonium acetate was not in accordance with what was generally supposed to be the difference in the action of potassium and ammonium salts.—Mr. Mahomed, in his reply, thanked the members for their patient hearing of a paper which was chiefly theoretical. He was not surprised that members would like facts and a basis for his estimation of drugs. So would he. What could even the most distinguished authors provide in this direction? Scarcely anything. Physiological experiments were very little guide. Replying to Dr. Gilbert he said that he ranked acetate of potassium high as a diaphoretic from results of practice. He found that if a good dose of it were exhibited in about three days most patients noticed considerable perspirations. Few drugs would do that except pilocarpin and salicylate of soda which required the patient to be kept in bed.

Chelsea Clinical Society.—A meeting of this society was held on April 16th, Dr. William Ewart, the President, being in the chair.—Mr. J. Foster Palmer read a paper on Cystic Disease of the Chorion. After describing the views formerly held as to the pathology of this condition and pointing out their erroneous nature Mr. Palmer gave a brief sketch of the views now held on the subject, mentioning especially the names of Gierse and Meckel, who inclined to the theory that the death of the fœtus was the cause of this degeneration, while Paget and Mettenheimer maintained that the degeneration was the cause of the death of the fœtus. Attention was also drawn to the morbid proliferating power of the cysts. Mr. Palmer then described two cases which had been under his care in 1875 and 1876 respectively. The second of these cases was of interest on account of the fact that the phenomenon had occurred a second time, after 12 months' interval, with a doubtful history of abortion between. Bearing in mind the very doubtful nature of this so-called abortion Mr. Palmer was inclined to the opinion that the second mole pregnancy might possibly have been a continuation of the first owing to a few of the cystic villi having been left behind and having thus become proliferated, in which case a nice medico-legal question might arise as to whether hydatid moles were necessarily a proof of conception having taken place even within 12 months or more.—A discussion followed, in which the President and Dr. Vincent Dickinson took part.—Dr. Barry Blacker read a paper on Light Treatment. After alluding to the fact that in very early times light rays were employed mainly in conjunction with heat, the agent being the rays from the sun, and that electricity had been found to be more easily relied upon in this country and perhaps had had a decidedly increased effect due to the fact that it contained certain rays which were not found in sunlight when it reached the earth, Dr. Blacker gave a description of light treatment abroad and emphasis was placed upon the difference to be observed between the action of light and heat rays, both of which had been proved, in his opinion, to be useful in treatment, either separately or in combination, but both if used indiscriminately produced harmful results. There were four methods of employing electricity in light treatment: (1) diffuse light; (2) heat and light combined; (3) intense light; and (4) concentrated light, the last-named method being associated with the name of Professor Finsen. A description was then given of the manner in which these different methods might be employed. In the diffuse light exposures the patient should be without clothes and the temperature should not rise above 98° F., and to commence with the duration of the exposure should not exceed 10 minutes, as it might produce great distress, and the maximum should be 30 minutes. The effects observed were slight increase in the pulse-rate, a rise of two or three degrees in the body temperature, irritability and excitement, which, however, soon passed off if the exposure were not too prolonged, followed by drowsiness, lassitude, and prostration, with fulness in the head. The respirations became fuller and deeper. When the exposure was too long and sudden sleeplessness might result, but when it was carefully regulated drowsiness and a refreshing sleep were produced, making it of value in insomnia. Heat and light in combination might be arranged in any desirable degree of intensity, rheumatic affections being without exception benefited by the addition of heat rays, and in cases of neuritis patients had only to try the addition of the proper proportion of light to appreciate the difference it made after having tried heat alone. The action of light was not passing, but it persisted for a long time after the exposures had been finished, and the effect in cases of overwork where a more complete change of environment could not be made was very marked. Of the various causes which received benefit from the action of light to the whole surface of the body none were more marked than those of exophthalmic goitre. Intense light was produced by the rays from an arc lamp of from 25 to 30 ampères and from 50 to 60 volts, the temperature required being regulated by the distance from the lamp; thus at a distance of 50 inches it was about 260° F., and at four yards about 75° F. This was the most satisfactory treatment for old rheumatic joints and all articular effusions. Emphasis was placed upon the great benefit derived by this particular form of light treatment in the relief of pain and neuralgic conditions generally. As regards treatment by concentrated light a description and demonstration of Professor Finsen's apparatus were given, also the method of the employment in the treatment of skin diseases, followed by an exhibition of cases so treated, with lantern slides.—A discussion followed.

Clinical Society of Manchester.—A meeting of this society was held on April 16th, Mr. F. A. Southam, the President, being in the chair.—Dr. E. S. Yonge showed two cases in which he had recently performed Asch's Operation for Deflected Nasal Septum with good effects. Operations for deflected septum were frequently disappointing, and the favourable results of Asch's method were mainly attributable to the fact that the resiliency of the septum was destroyed before that structure was straightened.—Mr. E. Stanmore Bishop showed a case of Fibromyoma occurring in a Semi-cornuate Uterus (removed by Baer's operation). The patient was also shown.—In conjunction with Dr. R. A. Paton, Mr. Bishop also showed a large Fibrocystic Uterus, weighing 19 pounds, which was removed by total abdominal hysterectomy on March 20th with a successful result.—Dr. J. W. Stenhouse brought before the meeting several cases of Toxæmia. The first case was that of a primipara, aged 22 years, in which the main symptoms were mental. Towards the end of her pregnancy she began to exhibit mental symptoms, but two days after her confinement, which was perfectly normal, she became melancholic. With the accession of milk the melancholy deepened, and on the fifth day it gradually changed to mania and she died delirious on the eighth day. The pulse and temperature were normal till she became maniacal. Treatment had no effect. The second case was that of a married woman, aged 23 years, who passed through her first pregnancy without incident. In the sixth month of her second pregnancy she noticed that the skin on her chest and breasts became spotted with a reddish-brown discolouration. She aborted at the seventh month and the pigmentation disappeared. Three months after she became pregnant again and the discolouration reappeared and extended downwards like an inverted cone on to her abdomen. She felt ill and weak and had a brownish discharge. She aborted about the third month. The pigmentation became fainter, but at every menstrual period it became much darker. It finally disappeared under the influence of arsenic. The third case was one in which the patient had convulsions at her first confinement. She had had two pregnancies since and each time albumin had appeared in the urine in the seventh month. Under treatment the pregnancies had terminated without incident. The fourth case was brought before the society last year. The specific gravity of the urine had remained persistently low, though the albumin had disappeared. The fifth case occurred in a primipara, aged 30 years. When first seen she was about eight months pregnant. The legs were œdematous, the face and hands were puffed, and she complained of headache, of pains and pricking, and of numbness in the extremities. The liver was slightly enlarged and very tender on pressure. The heart was normal. The specific gravity of the urine was 1008 and semi-solid with albumin. She was ordered to bed, put on a milk diet, and given calomel and salts. The urine was very slow in showing any change. In a fortnight the albumin was slightly less and the specific gravity was 1004. In the fortnight preceding the confinement it rapidly altered; the albumin got less and the specific gravity rose to from 1014 to 1018. The pregnancy terminated without incident and was instrumental. Four months after there was still some tenderness of the liver as well as a trace of albumin in the urine, and the specific gravity was 1016.—Dr. W. E. Fothergill opened the discussion, in which Dr. E. Vipont Brown, Dr. W. Graham, and Dr. A. Fraser took part.

Reviews and Notices of Books.

Diseases of the Heart: a Clinical Text-book for the Use of Students and Practitioners of Medicine. By EDMUND HENRY COLBECK, B.A., M.D. Cantab., &c. London: Methuen and Co. 1901. Pp. 350. Price 12s.

THE author of this work set himself the task of producing "a book dealing with the clinical side of the subject of heart disease in a form suitable to the requirements of the student and newly qualified practitioner of medicine." He has consequently entered very fully into the elementary anatomy, physiology, and methods of diagnosis of diseases of the heart before dealing in detail with the various affections themselves and their treatment. It seems part of the nature of a "text-book" that such matters should be considered *ab infero et imo*, and there is much scope for the exercise of judgment in executing such a task. The continual advance in the knowledge of anatomical and physiological details, as well as in other departments of such a study as that with which this book is concerned, renders it desirable that a well-sifted compendium of such knowledge should from time to time be made accessible. Such a work is particularly useful to the busy practitioner of medicine who has little time for, and not much opportunity of, keeping himself *au courant* with the researches of those who have more leisure for original investigation. In, view, also, of the amount and multifarious nature of the material which the student of to-day has to compress into his medical curriculum, such a digest is calculated to prove of service. It may be questioned, however, whether the student would not be better occupied in making his own, by reference to larger sources of information, much of the preliminary matter set forth in such special text-books as the present.

On such points opinions may legitimately differ. The author believes that such a work is calculated to be of service to both classes for which he writes, and we are glad to be able to state that in our opinion he has exercised all the judgment, care, and method necessary in the execution of his task to fulfil his purpose He has avoided much "controversial matter" to gain "greater precision" in the exposition of the subject. In this he has no doubt been wise, for much of such matter is both crude and ephemeral. His description, however, of the sympathetic endowment of the heart appears to us to be scarcely consonant with present views on the subject. We are under the impression that the sympathetic outflow to the heart, at any rate in the higher mammals, has been fairly well established to be from the lower, not from the middle and upper, cervical ganglia. The diagrams given of the cardiac cycle are more elaborate than their prototype first employed by Sir William Gairdner, and the elaboration does not appear to us to be advantageous. On the other hand, the author's diagrammatic explanation of the arterial transformations in the fœtus, which appropriately precedes his consideration of congenital affections of the heart, is one of the simplest and best with which we are acquainted. These affections are somewhat fully treated by the author and we have nothing but praise both for the matter and the manner of his handling of the subject. The admitted difficulty in the precise diagnosis of some of these lesions constitutes it one of the still uncultivated fields of physical diagnostic exploration, and its fuller treatment in this book than in some larger treatises is calculated to stimulate the ingenuity both of students and practitioners. The author likewise gives more than a passing notice to lesions of the pulmonary valves, once designated the "region of romance," and in doing so chronicles an important advance in the knowledge of affections of the heart, for the physics of the dextral circulation differ considerably from those of the sinistral heart. Diseases of the left side of the heart are treated with the fulness and care which their frequency and importance demand, and the elements of their diagnosis and prognosis are considered with both judgment and perspicacity.

Special sections are devoted to the estimation of reflux and impeded afflux in regurgitant and obstructive lesions, an emphasising of these points which is of theoretic interest and practical importance. The author mentions a fact which is frequently ignored—namely, that although the character of the bruit may have no fixed relation to the amount of lesion, it is important as an index to ventricular force. When, however, he states, in discussing mitral incompetence (p. 179) that the total obscuration of the first sound by bruit and its conduction in the recognised direction may be taken to indicate that the "amount of regurgitation is very considerable," we do not think sufficient weight is given to the fact that the *loudness* of the bruit may obscure the first sound at its site of maximum intensity, without its being necessarily an index to the amount of regurgitation. A chapter is specially devoted to the consideration of angina pectoris, a subject which has exercised a fascination for many writers on cardiac pathology and therapeutics, and the reader will find here a short yet good *résumé* of present knowledge on this important affection, the essential nature of which is still somewhat mysterious. The book closes with observations on the Nature and Treatment of Functional Disorders of the Heart. Bearing in mind the avowed object which the author had in collecting and weighing his material we can congratulate him on having effected his purpose in a manner which should prove satisfactory and helpful to the majority of his readers. Modest as is the aim of the book, we consider that Dr. Colbeck has produced a work of more intrinsic value than some more pretentious volumes.

Die Lepra. By Dr VICTOR BABES. Vol. XXIV. of Professor Nothnagel's Special Pathology and Therapeutics. Vienna: Alfred Hölder. 1901. Pp. 350. Illustrated. Price 10 marks 60 pfennigs.

THE volume under review constitutes one of the latest additions to Professor Nothnagel's System of Special Pathology and Therapeutics, and probably there is no authority in Europe better entitled to undertake this particular section than Dr. Victor Babes, whose name is a familiar one in the literature of the subject. In Roumania, where his researches have for the most part been conducted, leprosy is by no means uncommon, so that he has had the advantage of clinical experience as well as having had ample pathological material from which to draw his conclusions.

Dr. Babes has freely availed himself of the great mass of evidence collected from all parts of the world and published in the somewhat chaotic reports of the Berlin Conference of 1897. The knowledge thus acquired he has summarised in a most masterly manner and combined with the results of his own experience. He has completed a work on leprosy which may be regarded as the standard work on the subject. The history of the disease and its geographical distribution are dealt with in the first and second chapters. Then follow those on the etiology, pathology, symptomatology, diagnosis, and treatment. The pathology of the disease may be said to date from the discovery of the bacillus by Neisser in 1897, for to this investigator and not to Hansen the author gives the credit of the discovery. Hansen, working under the disadvantage of unstained preparations, was too indefinite in his despriptions to rank as the real discoverer. Considerable space is devoted to the methods by which the disease may be propagated and the question of hereditary transmission. The long incubation period necessary for the full parasitic development of the bacillus is a serious obstacle to experimental inoculation and renders it difficult to learn definitely by what path or paths the bacillus enters the human system. The author believes that though hereditary transmission may occasionally take place, as a general rule it plays but a small part in the spread of the disease. That leprosy partakes of the nature of a family disease, in the sense that all the members of a family may be infected, the author regards as admitting of no doubt; but since it frequently happens that the offspring show symptoms before the parents it is difficult to prove that in any particular case the children have acquired from the parents either a predisposition to the disease or the disease in an hereditary form. As regards treatment, Dr. Babes has faith in the eventual discovery of a specific serum; in the meanwhile, he claims advantage for his anti-tuberculous and anti-diphtheritic methods. He believes that we shall overcome the difficulties of understanding the true nature of the disease by studying the bacillus in its exogenous or saprophytic form rather than by confining our attention to it as a parasite in the human body. He suggests that it may possess a very complicated cycle of development, possibly in plants, manure, and fishes. The life-history of the bacilli of tubercle, diphtheria, and leprosy presents analogies and similarities which Dr. Babes evidently regards as of extreme interest and importance. It is to be hoped that this admirable work will be translated into English for the benefit specially of those of our colonial brethren who cannot read with facility the technical writings of a German *savant*.

Hygiene and Public Health. By LOUIS C. PARKES, M.D., D.P.H. Lond., and HENRY R. KENWOOD, M.B. Edin., D.P.H., F.C.S. London: H. K. Lewis. 1901. Price 12*s*.

THIS work, which consists of 732 pages, is practically an expansion of "Hygiene and Public Health," by Dr. Louis Parkes, which was published in 1889 and which has since run through five editions. Dr. Kenwood has now joined Dr. Parkes in authorship and the result is a considerable expansion both in the size and scope of the original volume. In a book of this nature the reader naturally turns to the subjects upon which the advance of science has recently thrown most light or concerning which the legislature has added to the statutes—such, for instance, as the purification of sewage, the natural history of infectious disease, and disinfection. In all these particulars the book before us has been brought well up to date, and the present position of our knowledge is set forth in a very readable fashion. The character of the several chapters varies somewhat—that upon water being excellent, while that upon meteorology is, in our view, a little too much expanded for the general character of the book. In other cases there might have been more concentration, but as a matter of fact the student, for whom of course the book is largely intended, does not like his information too much boiled down. The last chapter deals with sanitary law and administration, and although the space given to this subject is small the matter is well arranged. We notice, however, that under the heading of "Rivers Pollution" the administration of the Rivers Pollution Act is somewhat insufficiently set forth. The sanction of the Local Government Board is, we think, only necessary under Part III. of the Act, and not under the whole Act, as is implied. Some mention, too, should have been made of the powers of county councils under this heading. The book will not only serve the student's purpose but it will form a useful focus of our present knowledge for the medical officer of health. A wholesome scientific spirit pervades the work.

Uterine Tumours, their Pathology and Treatment. By W. ROGER WILLIAMS, F.R.C.S. Eng. With 58 Illustrations. Demy 8vo. London: Baillière, Tindall, and Cox. 1901. Pp. xvi.-360. Price 10*s*. 6*d*. net.

IN his preface to this book Mr. Roger Williams quotes Buckle as saying, with reference to medical literature: "We are in the predicament that our facts have outstripped our knowledge, and are now encumbering our march." That this is so is without question. In an endeavour to restore some order to the chaotic mass of facts known to us with regard to uterine tumours the author has written this monograph. The close attention that Mr. Roger Williams has given to this subject renders him well fitted to attempt such a task. The greater part of the book is, of course, taken up with myomata and carcinomata of the uterus. Amongst some of the most interesting chapters and sections are those upon the Pathogenesis of Myomata, their Biology, the Question of the Origin of Malignant from Myomatous Tumours, and the Radical Treatment of Myomata.

With regard to the origin of these tumours the conclusion is come to that it is connected with abnormal development of the musculature, detached fragments of which—grouped round heterotopic epithelial "rests"—are the germs whence they arise.

The author clearly shows that far from myomata having any special proclivity to become cancerous they are very much less liable to originate this disease than are the glandular elements of the uterus itself, while from the data collected it is evident that such tumours seldom become sarcomatous. These conclusions are of great value in view of the statement that is so often made that uterine myomata tend to become malignant. In reference to their etiology the great importance to be laid upon the suppression of maternity and diminution of the natural fertility is clearly shown. Grave exception has been taken to Mr. Roger Williams's statement that "if the practice of some surgeons—in removing myomata whenever recognisable—were generally followed nearly 1,000,000 operations of this kind might be done in a single year, and as the average mortality from such operations may be estimated at about 10 per cent. this means that about 100,000 lives would be sacrificed in a single year." That the mortality of such operations would probably be much less than 10 per cent. and that such a statement is an exaggerated one is no doubt true, yet it well tends to show how great a responsibility lies with those who lightly recommend operation for a condition the normal mortality from which may be regarded as about 1 in 2000 cases. We should be better able to come to a decision upon this most important matter if those surgeons who operate upon large numbers of fibromyomata would state clearly and definitely in every case what were the indications for operation.

The second part of the book is concerned with Malignant Tumours of the Uterus. Mr. Roger Williams's views upon the etiology of cancer are of much interest. He has collected a large amount of evidence tending to prove Moore's statement "that cancer is eminently a disease of persons whose previous life has been healthy and whose nutritive vigour gives them otherwise a prospect of long life." From the considerations brought forward he concludes that the disease is prevalent mainly amongst the well-to-do and easy-going who habitually eat more than is good for them. An observation of much importance is that of 137 patients under observation with cancer of the uterus only 13 had suffered from previous disease of that organ—viz., leucorrhœa, seven; prolapse, three; and endometritis, three.

There are many other interesting observations for the consideration of which we must refer our readers to the book itself. The amount of material dealt with is enormous, including as it does not only the author's own experience but also a large number of references to foreign literature. We can cordially congratulate Mr. Roger Williams upon the production of an eminently readable book and one which will probably long remain as the best monograph upon the subject.

LIBRARY TABLE.

Electro-Hæmostasis in Operative Surgery. By ALEXANDER J. C. SKENE, M.D. London: Henry Kimpton. 1901. Pp. 160. Price 10*s.* 6*d.* net.—We learn from Dr. Skene's preface that this work was issued to supplement the third edition of his book on diseases of women. The greater part of it therefore deals with gynæcological surgery. At the outset we may remark that we think that the title is badly chosen. The hæmostatic agent is not electricity but heat, albeit the source of heat is electricity. Dr. Skene's method is, in fact, an adaptation, and a very useful one, of the ordinary cautery. The advantages of the electrical cautery are, of course, that the instrument can be placed in position when cold, that the degree of heat can be exactly regulated, and that the heat can be practically instantaneously cut off. The vessels are not burned but simply cooked—that is to say, their albuminous constituents are coagulated and the walls are fused together. Dr. Skene gives a detailed account of the use of this method in various operations, and the book concludes with two chapters upon Asepsis and Antisepsis. Altogether a study of the cases cited by Dr. Skene shows the great superiority of this method of hæmostasis over ligatures, however carefully sterilised these latter may be.

Appendix XIV. to the Second Edition of the Descriptive Catalogue of the Pathological Specimens contained in the Museum of the Royal College of Surgeons of England. By SAMUEL G. SHATTOCK, Pathological Curator of the Museum. London: Printed and sold for the College by Taylor and Francis. 1900. Pp. 56.—This appendix contains descriptions of the pathological specimens added to the Museum during the year ending July 1st, 1900. As might be expected, a number of the specimens deal with gunshot wounds and the missiles inflicting them. A very interesting and uncommon specimen is shown in Number 599A, which illustrates the conditions found in the right forearm and hand of a chimpanzee. The tendons of the flexor profundus digitorum were ruptured near their insertion into the terminal phalanges. The tendon of the index was tied in a knot around the unruptured tendon of the flexor sublimis, after having been withdrawn completely through the slit in the latter.

La Mécanothérapie. Par le Dr. L. R. REGNIER. (*Mechanotherapy.* By Dr. L. R. REGNIER.) Paris: J. B. Baillière et Fils. 1901. Pp. 92. Price 1 franc 50 centimes.—This little book forms one of a series entitled "Les Actualités Medicales," and to give it its extended title is an account of the application of movement to the cure of diseases. Dr. Regnier is the physician in charge of the electrical department at the Charity Hospital in Paris and probably, therefore, has a wide experience of that class of patients which includes those obviously suffering from something but who present no very definite symptoms. Such patients, be they "neurasthenic" or not, generally end up in the electrical department and without doubt get great relief from properly carried out exercises and massage. In addition to such cases those patients suffering from disorders of nutrition, commencing lateral curvature, and certain forms of morbus cordis are undoubtedly greatly benefited by exercises. Dr. Regnier gives a clear account of the various apparatus and exercises and the methods of applying them. Any practitioner wishing to make himself acquainted with mechanotherapeutics will be enlightened by a study of the book now before us.

Science and Mediæval Thought. By THOMAS CLIFFORD ALLBUTT, M.A., M.D. Cantab. London: C. J. Clay and Sons. 1901. Pp. 116. Price 2*s.* 6*d.* net.—This is a reprint of the Harveian Oration delivered before the Royal College of Physicians of London on St. Luke's Day, Oct. 18th, 1900, and of which an abstract appeared in THE LANCET of Oct. 27th, 1900, p. 1179. It is a scholarly and learned review of some aspects of mediæval thought and of the influences which withstood Harvey in his works, in his discoveries, and in the acceptation of them. Arid and erroneous as in many ways was mediæval philosophical thought, yet, as Professor Clifford Allbutt finely says in his introduction, "Their many errors came not of indolence, for they were passionate; not of hatred of light, for they were eager for the light; not of fickleness, for they wrought with unparalleled devotion; nor, indeed, of ignorance of particular things, for they knew many things; they erred because they did not know, and they could not know, the conditions of the problems which ...... they were nevertheless bound to attack." The dread of change was one great obstacle in Harvey's way, and yet from the discussions and the troublings of mediæval minds seeking the truth and believing that they had found it was possibly bred that cast of mind which, in the bodies of Galileo, of Copernicus, of Kepler, and of Harvey, gave rise to those discoveries which revolutionised the conceptions hitherto held of the universe and of the many problems connected with life.

The Annual Charities Register and Digest for 1901. With an introduction by C. S. LOCH. London: Longmans, Green, and Co.—The current issue of this invaluable work gives a succinct account of every "charity" worthy of the name and of some among the "spiritual institutions" which, in our opinion, have *no* right to the name. Mr. C. S. Loch of the Charity Organisation Society contributes a most interesting introduction and the value of the book is further enhanced by an elaborate index. Ill-given alms are capable of doing incalculable harm, but a consultation of this book should go far in helping the almsgiver to distribute his charity with reason.

How to Read the Money Article. By C. DUGUID. Second edition. London: Effingham Wilson. 1901. Pp. 138. Price 2*s.* 6*d.*—This is a very useful little book, and when the author says that any city editor could easily have written it he makes too light of his accomplishment. Doubtless no one could fill the post of a city editor who had not at his finger's ends the information given in Mr. Duguid's pages, but it is not everybody who knows a technical subject well that can impart his knowledge well. On the contrary, fulness of knowledge is sometimes apt to lead to loss of proportion in the presentation of different points, to obscurity where the writer assumes in his readers too much knowledge, and to weariness where the writer, taking an exactly opposite course, considers it his duty to instruct his audience on matters of common elementary experience. These various pitfalls are neatly avoided by Mr. Duguid who in teaching us to understand the money article of the daily press incidentally gives the ordinary investor much valuable information. There has been a great growth in the number of companies of recent years and this extension of the limited liability system to all sorts of concerns has been enormously increased by what Mr. Duguid calls "the apotheosis of the one-pound share." Amateur financiers have now become so numerous in the land that we are sure many of our readers must be among their body. If they intend to watch over their own pecuniary interests they ought to know the lessons of this little book, but they must understand that ability to read the money article with intelligence will not make it prudent for them to embark upon investment without expert advice.

JOURNALS AND MAGAZINES.

La Grèce Médicale.—The opening article of the March number is by Dr. Raynardt of Paris and is a biographical sketch of Dr. John A. Foustanos of Syra, the editor. Dr. Foustanos was born in Sparta in 1856 and took a medical degree at Athens in 1881, after which he served for a year as a medical officer in the Greek army, and then passed three years in medical study in Paris. On returning to Greece he settled in practice in Syra, became the correspondent of the Paris *Semaine Médicale*, was appointed director of the pathological department of the hospital, and wrote treatises on hypnotism and on new remedies, as well as a number of clinical reports of cases. His chief work, however, was the founding of two monthly medical journals, the only medical journals at present existing in Greece—namely, 'Ιατρική Πρόοδος (*Progrès Médical*), published in the Greek language, and *La Grèce Médicale*, published in French. In THE LANCET of August 11th, 1900, p. 454, we mentioned that Dr. Foustanos took part in the International Congress of the Medical Press held in Paris, and THE LANCET of Oct. 6th, 1900, p. 1047, contained a short history of medical journalism in Greece since the year 1836. The biography of Dr. Foustanos is illustrated with a portrait in which he is shown wearing the decoration of the Order of the Saviour conferred on him by the Greek Government.

Praeco Latinus.—Although not in any way relating to medicine, this monthly serial of 32 pages, the size of which is a little smaller than those of THE LANCET, deserves notice as a curiosity in journalism. Not the title only, but the whole of the contents, are in Latin and on the covers there are full-page advertisements of an American firm of tool-makers, a nail-maker, a hatter, and the Hammond typewriter all in the same language. Among the various articles in the January number may be mentioned a poem by the Pope, an instalment of a translation of Silvio Pellico's well-known work "Le mie Prigioni," and a description of Admiral Dewey's reception on his return from the war with Spain; there are also correspondence columns. Many might feel a certain amount of interest in a periodical of this kind. *Praeco Latinus* is copiously illustrated, chiefly with views in Rome, the frontispiece being a fine portrait of the Pope. All communications are to be sent to Letter Box 228, Philadelphia, U.S. of America. The annual subscription for countries other than America is $1.74, or 6*s.* 10*d.*

FROM
THE LANCET LABORATORY.

TABLOIDS: (1) SODIUM BISULPHATE; (2) BENZOIC ACID COMPOUND; AND (3) ERGOTIN.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

THE tabloid of sodium bisulphate is the outcome of the suggestion that this salt may be used for sterilising water infected with the enteric bacillus. A paper on this subject by Dr. L. C. Parkes and Dr. S. Rideal, F.I.C., appeared in THE LANCET of Jan. 26th, 1901, p. 234. It appears that a solution of sodium bisulphate in the proportion of one gramme of the salt to a pint of water is capable of destroying the typhoid bacillus after 15 minutes' contact. Water containing this small proportion of the salt does not appear to be unpalatable whilst possessing a slightly acidulous taste. The convenience of the tabloid for this purpose is obvious. Three tabloids are sufficient for one pint of water. The effect, however, of regularly taking this salt has not yet been completely ascertained. Doubtless the laxative effect would be slight, but it is maintained by some that the sulphates in plastered wines are responsible for cirrhosis. This, however, in our opinion is not probable Each tabloid contains five grains of the acid salt. The tabloid benzoic acid compound is based upon the following excellent formula: benzoic acid, half a grain; codeine, one-tenth of a grain; menthol, one-tenth of a grain; powdered ipecacuanha, one-tenth of a grain; cocaine hydrochloride, one-fortieth of a grain; and of red gum a sufficiency. A glance at this formula will show that the tabloid possesses expectorant properties and may act locally as a mild anæsthetic and astringent. The ergotin tabloid contains one grain of the hæmostatic principle. The tabloid is sugar-coated and is prepared from a reliable extract of known therapeutic efficiency.

GLOBINAL.

(F. WILLIAMS AND CO., 83, UPPER THAMES STREET, LONDON, E.C., AND WILCOX, JOZEAU, AND CO., 49, HAYMARKET, S.W.)

Globinal is described as a natural albuminate of iron and our analysis confirms the description. The substance is contained in capsules in the form of reddish-black scales which are easily soluble in cold water, yielding a blood-red solution. The solution shows two absorption bands when examined by the spectroscope identical with hæmoglobin. Our analysis was as follows: mineral matter, 2·90 per cent., containing 0·25 per cent. iron, the balance being due to other blood salts; albumin, 83·70 per cent.; and moisture, 13·40 per cent. Globinal may therefore be regarded as a highly nutritive hæmatinic. Albuminate of iron is without the drawbacks of ordinary iron preparations and does not affect the teeth or give rise to constipation. Its administration improves the powers of nutrition and thus globinal has been administered favourably in neurasthenia, anæmia, and chlorosis.

SYRUP OF GLYCEROPHOSPHATES.

(WYLEY'S, LIMITED, COVENTRY.)

This is a somewhat brilliantly-coloured syrup with characteristic saline taste. The glycerophosphates are contained in the fluid unimpaired and are permanent on account of the concentrated state of the syrup. Each fluid drachm contains three grains of the combined dry glycerophosphates of lime, soda, potassium, iron, and magnesia. As is well known, the administration of the glycerophosphates has given favourable results in disorders of the processes of nutrition. The fact that lecithin, which is contained in the nervous tissues and blood corpuscles, splits up into choline and glycerophosphoric acid during digestion has suggested the administration of glycerophosphates in nervous diseases.

THE LANCET.

LONDON: SATURDAY, MAY 4, 1901.

The Home Office and Medical Witnesses' Fees.

THE reply of Mr. RITCHIE to the question put to him recently in the House of Commons by Mr. W. F LAWRENCE, Member of Parliament for the Abercromby division of Liverpool, with regard to the fees of medical witnesses, has intensified the feeling of dissatisfaction among members of the medical profession. Mr. RITCHIE practically admitted that medical witnesses in England and Wales were remunerated at a lower scale than their brethren in Scotland or Ireland. However, he not only held out no intention of attempting to remedy so substantial a grievance, but declined to make inquiry. He adopted, in fact, the attitude of most of his predecessors in office, especially Sir MATTHEW WHITE RIDLEY and Mr ASQUITH The latter gentleman admitted to a deputation from the United Kingdom Police Surgeons' Association that the fees were inadequate and that his predecessors had allowed the same, but that not one had liked to raise the scale and that he had no wish to burn his fingers by doing so. It is contrary to reason and justice that the members of the medical profession, any one of whom is liable to be called as a witness in a court of law, should remain passive under such a long standing grievance. In dealing with the matter again at some length we know that we must be recapitulating what has already appeared in former articles, but we have no objection to repeating ourselves if good will come of it.

Medical practitioners have in many cases been summoned before magistrates to give evidence in cases which have been disposed of summarily, and on demanding a fee for their attendance and loss of time have been calmly informed by the presiding magistrate that there are no funds at his disposal for the purpose. In some large towns a fee of half a guinea is allowed in such cases, but only for one attendance. This, we submit, constitutes in itself a grievance which demands an inquiry. Passing on to those cases which go to a higher court and may for convenience be called "committal cases" the scale of fees is that fixed in 1858 Under this scale a fee of half a guinea per diem is allowed for attendance in the police-court, these fees being payable after the conclusion of the trial at sessions or assizes So far from being a just or adequate fee its offer is an insult to the medical profession. In the sessions and the assizes courts the fee is one guinea each day, a very insufficient sum for being present all day in court, even if the medical witness happens to reside in the city or town where the assizes or sessions are held. Should he be required to proceed to a court of sessions or an assize court held at a distance he receives the same fee with railway fare each way and an allowance of 2*s.* per night. Formerly first-class railway fares were allowed; now we learn that only second-class, and even third class, fares are given. It requires some effort to think and to write calmly on *this point, especially when the reason* why the medical witness has been drawn into the case at all is considered. Most probably he has been hastily called to a person seriously injured or suffering from symptoms of poisoning in which his prompt attendance is dictated by feelings of humanity regardless of any question of fee. Once in attendance he becomes a witness of facts to which he is required to testify before the coroner and the magistrate. By both these officials he is bound over in a heavy recognisance which compels him to be present at the assizes, leaving all questions of remuneration to the powers that be. Again, the medical witness may have been called to see a dead body, found under suspicious circumstances. This must not and cannot be a mere perfunctory duty (though it is too often an unpaid one), since, as the late Lord DEAS, one of the Scotch judges, observed, a medical man when he sees a dead body should notice everything. Or it may be a case of criminal assault on a female or one of unnatural offence—cases as uninviting as any professional witness can be called to. In all these cases the medical witness must leave his patients in charge of a locum-tenent or brother practitioner and proceed to the *locale* of the assizes, being detained there for some days or it may be for a week. After receiving the fee of one guinea per day and the second- or third class railway fare and the allowance of 2*s.* per night, he finds himself on his return home, and having paid his locum-tenent, not only without any remuneration at all, but out of pocket to a considerable extent. For it is manifest that the allowance of 2*s.* per night will not suffice to pay a hotel bill, this must be paid out of the one guinea per day which is supposed to remunerate the medical witness for his attendance. *These facts—for facts they are of the most stubborn* character—demand a Government inquiry, and if this were held it would be shown that so far from the grievances of the medical witness having been overstated they have been expressed with moderation.

Sir GEORGE GREY fixed the present scale in 1858 In 1862, just four years later, the case of REG. *v.* CHARLTON was tried at Carlisle. It was a case of murder, the deceased woman having been murdered under circumstances of great brutality by an engine-driver who was not arrested until a month afterwards The evidence was circumstantial and the *medical* evidence formed a very important part of it. The late Mr. WILLIAM BOUSFIELD PAGE, the leading surgeon of Carlisle and the principal medical witness, demanded the sum of 12 guineas for his two days' attendance in court On its being refused he appealed to the presiding judge, the late Mr. Justice WILLES, who promptly ordered it to be paid. The learned judge's decision was probably stiffened, if not prompted, by what had previously occurred at the commencement of the trial. The prosecuting counsel for the Crown had complained that the costs of the prosecution had been so cut down that he had been unable to have a plan of the scene of the murder and had been obliged to accept one prepared for the defence The learned judge severely rebuked this cutting down process and on the official responsible for it rising in court and stating that the costs of plans were always allowed when necessary he was promptly silenced. "I beg your pardon," replied Mr. Justice WILLES, "in a case recently tried by my brother BYLES the costs of a plan were disallowed although he ordered it to be prepared himself." It is to the point and suggestive in conjunction with this to notice Mr. RITCHIE'S answer to Mr. LAWRENCE that any increase of medical witnesses' fees would lead to a great increase of the costs of prosecution. What does that matter? Why should not the truth be properly paid for?

In addition to the grievances of attendance at police, sessions, and assize courts for inadequate remuneration there is growing cause of complaint of the low fees paid for attendance at coroners' courts. Nor can it be surprising, for if the scale fixed in 1858 be insufficient, what must be said of that fixed in 1836 for the coroners' court and re-enacted in 1887 without any amendment and, so far as we can learn, without any protest from any Member, medical or lay, of the House of Commons? Is there no difference between the value of a guinea in 1836 and now? Is one guinea a reasonable fee for making post-mortem examinations and one guinea sufficient for attending an inquest twice, or it may be three times? The cry for reform all round in the matter of the remuneration of medical witnesses is outspoken. Will the present Government grant the very reasonable request that medical practitioners shall not be compelled to aid justice at a pecuniary cost to themselves? Will they refrain from discouraging the practice of medical jurisprudence by general practitioners of the present day? It is not only possible, but probable, that if the present obdurate attitude of the Home Office be not relaxed justice may in the near future be very seriously compromised.

The Medical Profession and the Budget.

MEDICAL men are not as a rule particularly interested in party politics, nor is it the function of a medical journal to join in the strife of contending statesmen. Medical men, however, are not exempt from the payment of taxes and are as directly concerned in the incidence of these imposts as are their fellow-citizens. It is fitting, therefore, that we should consider what the effects on the medical profession will be of the Budget proposals now before the House of Commons. It is our opinion that these proposals will press very hardly on medical men at a time when the profession can ill bear the strain. The fees which they obtain as the result of their intellectual work have not been increased, although during the last few years the cost of living has in many directions been raised and the cost of scientific education has been doubled. Hard-working general practitioners pay to the revenue an amount disproportionately large as compared with that paid by most other classes of the community, while they receive from the Government the scantiest recognition—almost no help—in their efforts to preserve the health of the people and to maintain a high standard of efficiency.

It unfortunately happens that many of the patients from whom our readers who are in general practice might expect to receive the bulk of their incomes are affected in the same way as the medical practitioners are affected by an increase in the income-tax, a tax which, as a matter of fact, is felt by the intellectually labouring classes and the lower middle classes more than by any other section of the community. The people who were once termed "the industrious classes," and whose present representatives are still called "the labouring classes," do not under the present conditions of life contribute their just proportion to the national exchequer. They are exempt from any payment of the income-tax, as a rule they pay nothing whatever for the education of their children, and they usually obtain medical treatment and medicine at no cost to themselves or at such a cost that the medical profession has had to object to the starvation terms offered to requite its services. To the rich the increase in the income-tax is an annoyance, but it is one which can be borne without any great measure of discomfort. We fear, however, that in the case of very many people with small incomes the increase will be a real hardship. We are convinced, by the way, from correspondence that we have received, that many medical practitioners at present pay income-tax on a larger amount than they need. Many men, especially those who live in the country, have a great objection to deal fully with their private business matters in a return which has to be sent to somebody who lives near and whose complete discretion they mistrust. To admit a decrease in their annual takings, they rightly or wrongly feel, would be dangerous, for the fact might leak out to their damage, and so they accept year after year a too high assessment. Again, like many other people, medical men we know frequently neglect to fill up the statutory declaration in regard to their incomes and are content to have the amounts assessed for them. This state of things often goes on year after year till the assessor increases the sum to be paid to an unreasonable amount. The trouble and the expense of an appeal are at length considered, though the consideration stage is as far as matters generally get. A careless or a busy man often pays more income-tax than he ought, partly because of the trouble unavoidably entailed in getting the matter righted and partly in some cases because he objects "to plead poverty"—as he explains the matter to himself. Doubtless much annoyance is necessarily caused when a gossip has charge of the collection of the income-tax, but it is our opinion that this is not common and that for the most part apprehension is groundless. Medical men would do well, when they object to their assessment and when they fear a leakage of their private affairs if they remonstrate with the local official, to apply to have their assessments made by the Special Commissioners under the provisions made for that purpose. A little trouble may at first be caused by this method of proceeding, but in the long run annoyance will be saved.

Even when medical men take the trouble to make their returns we know that many in estimating their net incomes do so in a way which is very favourable to the Inland Revenue. A shopkeeper looks upon the rent of his business premises as part of his necessary trade expenses. In like manner it is a necessary part of the trade expenses of a medical man to rent his house, or at any rate his surgery. If his surgery is separate from his house he pays no income-tax upon the rent of it. If his house is also his business address he pays no income-tax on two-thirds of the rent. Do all medical practitioners in estimating their taxable income take this matter into account? We know they do not, for we have had returns submitted to us where the error of making no allowances for rent had occurred. A shopkeeper who delivers goods rightly looks upon the cost of his carts and horses and carmen as part of the expenses of his business. Many medical practitioners who keep horses, carriages, and grooms to enable them to visit their patients do not keep proper accounts by which they can show which of the expenses thus entailed are absolutely necessary to their business inasmuch as without them the practice could not be carried on. They have only themselves to thank if they pay more than a fair contribution to the national chest

The Prospects of Plague in London.

THE occurrence last week of a suspected case of plague in London serves to remind us that the year may not pass away without the appearance of this disease in the London population. Plague has already been ship-borne to several English ports, and the appearance of the disease in the Cape, where Europeans as well as natives are being attacked, makes it probable that there will be further importations It is hardly to be expected that the vigilance of the port sanitary authorities will suffice to prevent attacks of persons resident in this country, while the free communication between London and South Africa makes the invasion of the metropolis a likely event.

The recent case is not, we understand, officially regarded as plague, but under the circumstances attention may reasonably be directed to the question whether the prevalence of plague, if it should come among us, will attain large proportions or whether it will be limited to localised outbreaks of inconsiderable importance. We think that there are ample reasons for believing that there will be no general prevalence and that the efficient performance of duty by the local authorities concerned will suffice to prevent any epidemic of magnitude. This opinion is necessarily based upon the past history of the disease. We read of its behaviour in London in the middle of the seventeenth century, when in some six months a large proportion of the population perished; we know the extent of its operations in recent years in India and other countries; and the lesson taught by the experience of 1665 accords with that derived from observations of the behaviour of the disease as it has revealed itself in many Oriental cities in our own time Plague is a disease manifesting an enormous power to attack persons living in conditions of filth and degradation, but possessing limited power to attack persons living under the better and cleaner conditions of the twentieth century. In India it has been practically limited to the native population, and in Glasgow it was last year limited to the lowest class of the population In London we may expect that it will observe much the same rule. If explanation is required for its large diffusion in 1665 it is no doubt to be found in the character of the population of London at that time and 20 years later, when, as MACAULAY tells us, "the pavement was detestable; all foreigners cried shame upon it. The drainage was so bad that in rainy weather the gutters soon became torrents Several facetious poets have commemorated the fury with which these black rivulets roared down Snow-hill and Ludgate hill, bearing to the Fleet Ditch a vast tribute of animal and vegetable filth from the stalls of butchers and greengrocers." The rich lived in luxury, but they were comparatively few in number and they were in intimate association with the crowds of poor and uncivilised people who made up the mass of the population. St. James's-square, occupied by wealthy peers, "was a receptacle for all the offal and cinders, for all the dead cats and dead dogs of Westminster." The conditions which now are seen to foster plague in Eastern countries were then everywhere present in London. These conditions have passed away. London still has its slums, but the worst have gone and only in small proportions is a population to be found comparable to that which made up the mass of the people in 1665 It is a somewhat striking fact that the London County Council is now engaged in the clearance of the Clare Market area which was the abode of fashionable people in the time of the Great Plague Conditions involving want of air and light, bad arrangement of the houses and streets which were then deemed adequate for the well-to-do are not now regarded as fit for the poorest of the population of modern London

This vast change which has come over the metropolis gives us an assurance of security which is the more reliable because we see in our own time that plague is able in the East to distinguish between the native and European races—the natives living under conditions which approximate to those of London in 1665 and the Europeans under conditions which resemble those of London at the present time. The extent to which plague may become prevalent in London will undoubtedly depend in some degree on the character which the disease assumes In this connexion it is deserving of note that plague in the year 1625 was much less destructive of human life than in 1665, although if any difference existed between the conditions of London in those two years it is probable that those of the earlier year were worse We have, however, now to reckon on an improved sanitary organisation, and this for the purposes of plague is fairly complete Precautionary measures against plague have been very properly taken by the London County Council in conjunction with the Metropolitan Asylums Board The measures suggested by the Public Health Committee of the Council were adopted at a meeting of the Council held on Tuesday last, April 30th. Every medical practitioner can now on application have from the London County Council the services of an expert to assist him in the diagnosis of any case presenting suspicious symptoms. Material from such cases will be subjected to precise bacteriological examination. Suspected as well as actual cases of plague will, on the certificate of the London County Council's expert, be isolated by the Metropolitan Asylums Board, and the Council will itself provide isolation houses for persons who have been exposed to plague, where they will be under medical inspection until such time as it can be determined that they have not been infected The investigations by the officers of the local sanitary authorities and the disinfection and destruction of infected articles should suffice to prevent an infected house becoming a source of further danger to the community. Interest will undoubtedly be felt in the increasing prevalence of plague at the Cape, and especially in the larger proportions of Europeans who have been attacked. It is probable that we shall learn later whether the cases have been of the pneumonic variety in larger proportion than in India. Should this form of disease make its appearance in England it will call for active treatment by the local authorities.

Annotations.

"Ne quid nimis."

MEDICAL OFFICER OF HEALTH AND PUBLIC ANALYST.

WE have consistently maintained that the posts of medical officer of health and public analyst in large districts or in the metropolitan boroughs should not be combined in the same person. The science and practice of sanitation are in themselves quite sufficient to occupy all the time of a medical officer who discharges his duties efficiently, in which case he would be prevented, in our opinion, from giving that systematic attention to laboratory work which is essential to the performance of the duties of a public analyst. Though we know that there are competent officers who combine both posts, yet we are convinced that the best work in both departments cannot, as a rule, be combined in the same person. The duties of a public analyst are very different from what they used to be: they demand much more of his time, greater skill, and more attention. The art of adulteration is more consummate than ever, and the public analyst must be more consummate than ever in order to detect adulteration; the medical officer of health cannot reasonably be expected to keep pace with modern methods of detecting fraud. Again, the number of samples hitherto taken under the Sale of Food and Drugs Act has been grossly inadequate—a fact which, as we have repeatedly shown, has done more than anything to maintain a high rate of adulteration. The duties of the medical officer of health should engage his time and attention to such an extent that to examine efficiently, say, 500 samples a year would be an impossibility. We do not think, therefore, that the municipal bodies are well-advised in combining the appointments of medical officer of health and public analyst. Such a combination is not for the public advantage. We were glad to learn that the Corporation of the City of London—though, we believe, under representations from the Local Government Board—decided on the death of the late Dr. Sedgwick Saunders, who was both the medical officer of health and the public analyst of the City of London, to separate the posts and to appoint two distinct persons. It has recently been disclosed that only 135 samples per annum were taken for analysis in the City of London—a number which was probably as much as the medical officer of health could examine in the time at his disposal. We trust that now a public analyst has been appointed separately the number of samples will be at least four times as much—or at any rate in accordance with the recommendation that at least one sample should be taken per 1000 of the population—and that the Local Government Board will press upon the corporation the desirability of taking an adequate number of samples. We feel sure that those authorities who have already decided to combine the posts of medical officer of health and public analyst in one person will ultimately find that they have established a wrong precedent—not because the medical officer is incompetent to make analyses, but because he has not the time to give to the analysis of food and drugs that specific attention which is desirable. As a rule, the duties of a medical officer of health are quite onerous enough in regard to sanitation without the additional burden of having to undertake the analysis of some hundreds of samples per annum of foods and drugs. Both departments, it seems to us, cannot be conducted by one person with that efficiency which in the public interest is desirable. Moreover, the best results are sure to be gained by two independent men, each with his special knowledge, acting in coöperation. The example of the City of London in separating the offices of medical officer of health and public analyst should be followed in all large districts, but that this is not to be the rule will appear from the following extracts from two advertisements which have appeared in the papers during the last few weeks.

> **Metropolitan Borough of Lewisham.**—APPOINTMENT of MEDICAL OFFICER of HEALTH and PUBLIC ANALYST.—Public Health (London) Act, 1891, and Sale of Food and Drugs Acts, 1875 to 1899.—Notice is hereby given that the Council of the Metropolitan Borough of Lewisham will, at their meeting on Wednesday, the 22nd May, 1901 (or at such adjournment thereof as may be resolved upon), proceed to the appointment of a duly qualified Medical Officer of Health and Public Analyst for the Borough, agreeably to the above-mentioned Acts, at a salary of £800 per annum—that is to say, £600 as Medical Officer of Health and £200 as Public Analyst, the Council to provide and furnish a Laboratory. ......
>
> The gentleman appointed must devote his whole time to the service of the Council and perform all the duties required of him by any Sanitary Acts of Parliament and the Sale of Food and Drugs Acts and such other professional duties as may from time to time be required of him by the Council.

> **Borough of Leicester.—Medical** OFFICER OF HEALTH and PUBLIC ANALYST.—The Corporation of Leicester are prepared to receive applications for the office of Medical Officer of Health for the Borough.
>
> The gentleman appointed must be a legally qualified medical practitioner, and hold a diploma in Sanitary Science or Public Health. He will be required to act as Medical Superintendent of the Isolation Hospital and (subsequent to the requisite confirmation) as Public Analyst and to devote the whole of his time to the duties of the office

It is interesting to add an extract from another advertisement which we have noticed this week. It runs as follows:—

> **Metropolitan Borough of Stepney.**—APPOINTMENT of ASSISTANT PUBLIC ANALYST.—The Council of the Metropolitan Borough of Stepney are prepared to receive applications for the appointment of an Assistant Public Analyst. The person appointed will be required to act under the direction of the Medical Officer of Health and Public Analyst and to devote the whole of his time to the duties of his office.

Evidently the Council of the Metropolitan Borough of Stepney have found it expedient to seek the services of an analyst so that their medical officer of health may be freer to attend to his own special duties, having occupied previously the combined post of public analyst and medical officer. We predict that other boroughs will find ultimately that they will have to adopt a similar course, and those who still have to make these appointments would do well if at the outset they appointed one man to the post of medical officer of health and another to the post of public analyst.

THE PUBLIC PROSECUTOR AND HIS INACTION.

A VERY interesting discussion took place in the House of Commons on April 26th at the instance of Mr. Goddard, the Member for Ipswich, who called attention to the staff of the Solicitor to the Treasury, King's Proctor, and Director of Public Prosecutions. Mr. Goddard pointed out that of 20 officers in the department six were either pluralists or were receiving salaries personal to the present holders of the positions. There were three assistant solicitors with salaries of £600 rising to £800. Of these three one was also Assistant King's Proctor and received for that position an additional £1000 a year. And now it was proposed to create an Assistant Director of Public Prosecutions—an entirely new office. There was much complaint of the inaction of the

Public Prosecutor, Mr. Caine, Sir Henry Fowler, and others being the critics. In this matter, as in most others, the complaint is not so much of the money spent, though that is serious enough, as of the inadequate service rendered to the public—the absence of a sufficient *quid pro quo*. Sir Robert Finlay gave the usual official support to the value of the work done by the Public Prosecutor and said that it was "admirably done." We are sorry that we cannot agree with the Attorney-General in this view. As medical journalists we have had much occasion to see the uselessness of this official and of his *entourage*. In the class of cases in which he has been asked to prosecute coming specially under our notice we have rarely seen any power displayed but the power of making excuses for doing nothing. The whole question of the work of this department needs investigation. Perhaps one of the reasons why the Director of Public Prosecutions so seldom sees his way to prosecute is the number of other offices he holds—he is also, we believe, Solicitor to the Admiralty, the Charity Commission, the Home Office, the Treasury, the War Office, and the Works Commission, and King's Proctor.

THE EARLY DIAGNOSIS OF MENTAL DISORDER.

PROFESSOR C. F. MACDONALD of New York University, formerly President of the New York State Commission in Lunacy, contributes to the first number of *American Medicine*, published on April 6th, 1901, a paper referring to the important subject of the early diagnosis of insanity. In the majority of cases, as he points out, the responsibility of recognising insanity in its early stages falls upon the family physician. While the occurrence of insanity in a family is fraught with serious, painful, and distressing circumstances to patient and relatives, to the community its continued increase means the provision of large public asylums and an increased expenditure of public money for the care and treatment of the insane. Thus the State of New York has at the present time, in round numbers, 22,000 insane persons under care, which implies an original capital outlay of 20,000,000 dollars for hospitals and their equipments, and an annual expenditure of 5,000,000 dollars for the care and treatment of the inmates. A considerable number of cases in the early stages of insanity may, especially among the wealthy classes, be properly and safely treated at home provided they are in competent medical hands. Insanity is a disease of gradual onset in most instances and the prodromal stage —that of alteration of conduct and character in contradistinction to that of actual mental aberration—may last for weeks or months. Relatives and friends are often the first to detect slight changes in character and lapses from the normal self, though they often make the mistake of attributing these to mere eccentricity or else they endeavour to conceal them or to make light of them in their ignorance. The prodromal symptoms of insanity are both somatic and psychical. The somatic symptoms include insomnia and headache, tinnitus aurium and vertigo, pavor nocturnus, feebleness of circulation in the extremities, anorexia, and constipation. The co-existence of persistent insomnia, constipation, and headache should always be regarded as serious, especially if they are associated with general apathy or mental irritability in a person previously active and well. The psychical symptoms may assume the form of undue exaltation and loquacity, levity of conduct in a person hitherto steady, depression of spirits, marked introspectiveness, hypersensitiveness of conscience, morbid aversion to friends, undue suspicion towards others, suicidal longings, and persistent forebodings of evil Any lapses from morality and decency in persons previously steady and well-behaved constitute warnings of a graver kind. If other predisposing factors co-exist, such as alcoholic or drug habits, cranial injury, sunstroke, epilepsy, prolonged mental anxiety, or recent ill-health, skilled medical advice should at once be sought. The presence of alcoholic intoxication, of delirium tremens, or the occurrence of meningitis or sunstroke, must be kept in mind as possibly masking or even simulating an attack of insanity. If hallucinations are present, and especially if delusions are associated therewith, the diagnosis of insanity would be confirmed. Special attention should be paid to the facial expression, the appearance and reaction of the pupils, the speech and handwriting, many of which are characteristically influenced in the early stages of mental disease. The importance of relieving insomnia, particularly if it is associated with slight mental depression and constipation, can hardly be over-estimated. Insomnia easily becomes a habit, and if allowed to go on unchecked it produces cerebral exhaustion and predisposes to mental disease. This threefold group of symptoms—viz , insomnia with mental depression and constipation, is so common at the onset of the acute psychoses that the experienced physician will anticipate the risk and seek by early treatment to avert the threatened attack.

LONG HOURS IN SHOPS.

AT the sitting of the Select Committee appointed by the House of Lords to consider the question of early closing for shops, which took place on April 29th, both Sir William S. Church, President of the Royal College of Physicians of London, and Sir William Mac Cormac, President of the Royal College of Surgeons of England, gave evidence. Both agreed that the hours in shops were too long and Sir William Church pointed out that the extent of injury depended not only on the length of time during which the shop assistants worked but also upon such matters as the ventilation, lighting, and condition of the buildings. Sir William Mac Cormac said that in his opinion the matter deserved the earnest attention of the Government. We are glad to see the leaders of the medical profession in England speaking out upon this matter, for it is one which is of the utmost importance to a very large body of our fellow-citizens. *The public do not seem to realise that supposing a* shop to open at 9 A.M. and to close at 7 P.M. it does not simply mean 10 hours' work for the assistants. It means something much more like 12 or 13 hours in many shops, particularly those of the drapery trade. Of course, as Sir William Church pointed out, in a small shop where there were no assistants but business was attended to by members of the family compulsory early closing would be unnecessary. But it is in the large establishments that legislation is called for.

THE PECULIAR PEOPLE AGAIN.

TWO members of the sect known as the Peculiar People were tried before Mr. Justice Phillimore at the last Old Bailey Sessions. Their case presented the features that have become so familiar in the criminal courts, and it occasioned the usual embarrassment when the question of punishment had to be decided. They had had 13 children, of whom five had died without receiving medical aid, and in the case of the fifth, an infant six months old suffering from pneumonia following whooping-cough, the "elder" had been summoned and he had pursued the usual course of anointing and prayer, but the child had died notwithstanding. It was, as is usual, impossible to prove in the sense required by the criminal law that the child would have lived had a medical man been in attendance, and so the charge of manslaughter was dropped and the parents were convicted of causing unnecessary suffering to their offspring. The male prisoner seems to have cross-examined the medical witness who had made the post-mortem examination as to whether if the prayer and the oil had caused cessation of pain there would have been evidence of this cessation of pain discoverable after death (to which he naturally received a negative answer), and he was no doubt genuinely imbued with a fanatical belief in the righteousness of his conduct. In the end, however, the jury convicted him and a fine of £20 was imposed and promptly paid, while the female prisoner, his wife, was bound over to come up for judgment if called upon, Mr. Justice Phillimore being of opinion that a more severe sentence would introduce an element of religious martyrdom into the proceedings. On the other hand, the danger of sentences being too light in such cases arises from the fact that it is an advantage to some parents to be able to get rid of their children, and that the risk of being fined may be worth incurring by people who may have no other motive for being "peculiar" than the desire to diminish their responsibilities with impunity. Whether an "elder" would detect such a motive and refuse to be called in by converts of this description we cannot say. At present the children of the Peculiar People do not constitute a large class, but they none the less deserve that the dangers to which they are exposed should be seriously considered.

REORGANISATION OF THE MEDICAL SERVICES OF THE AUXILIARY FORCES AND OF THE ARMY MEDICAL RESERVE.

WE have received a copy of the proceedings of the Conference on the Re-organisation of the Medical Services of the Auxiliary Forces and of the Army Medical Reserve, held on Dec. 19th, 1900, under the presidency of Professor Thomas Annandale, F.R.C.S. Edin., in which Professor Chiene and a number of officers of the volunteer forces, yeomanry, and volunteer medical staff corps took part. The conference was arranged by the East of Scotland Tactical Society. We are very glad to see that a movement of this kind has been started because the more light that is thrown upon the subject of medical aid in modern warfare and the more people are interested and the matter is discussed the better. The chairman opened the proceedings by adverting to the experience of the South African War and by giving a preliminary sketch of the objects which the society had in view and, as a teacher in an important medical school, he offered some remarks upon the training and position of the members of the Royal Army Medical Corps. He said that the members of that corps and the civil surgeons connected with them had done their duty nobly, and it was not with them that there was any dissatisfaction, there was, however, a general desire to assist the Government by carefully considered suggestions for the improvement and reform of the medical services of the regular army and reserve forces. The report of the Royal Commission on the Hospitals in South Africa not having been published, however, at the time the chairman and those taking part in the conference were labouring under the disadvantage of not knowing how matters stood. Professor Chiene remarked that if the civil surgeons who were to assist in time of war were to be apart from the volunteers then he held "a strong view that it should be an Imperial force, and that in the old country and in the colonies there should be men and women chosen for their special knowledge in the treatment of disease and injury, in the prevention of disease, and in the nursing of the sick. It appears to me that every hospital in the country should be asked to supply men as physicians and surgeons." We are glad to notice that Surgeon-Captain Hepburn, Edinburgh Company, Volunteer Medical Staff Corps, speaking of the men who enter the Army Medical Services, said that some time ago he took the trouble to look up the statistics of Edinburgh University for the last 15 years and he was surprised to find that a very large number of class medallists and demonstrators had gone into the home and Indian service and that the professional status of the men "sent into the medical service of the army was quite as good as any corresponding number of men sent into any other professional walk in life in the world." A number of volunteer medical officers took part in the discussion and many resolutions were passed, but the little pamphlet requires to be read *in extenso*, for it does not readily lend itself to analysis and criticism within a reasonable compass.

THE BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

IN our issue of April 27th, p. 1223, we noted that the Birmingham Consultative Medical and Surgical Institution had determined to advertise for two medical men in the place of Dr. H. Ward Irvine. We learn from the *Birmingham Gazette* of April 29th that the committee received a large number of answers from fully-qualified practitioners all over the country. The committee, however, were not satisfied with this response and they are now advertising for a physician, a surgeon, an oculist, an ear and throat specialist, and a gynæcologist. Again we wait with interest the result of the advertisement

SANITATION OF CHURCHES.

ACCORDING to the *Revue Scientifique* of April 27th one of the Italian bishops, Monsignor Franceschini, has sent to the clergy of his diocese a circular enjoining them to adopt sundry sanitary precautions in their churches. Immediately after saints' days, when the congregations have been large, the paved floors are to be cleansed with sawdust soaked in a solution of corrosive sublimate (1 in 1000). On ordinary occasions the floors are to be frequently swept, after a preliminary sprinkling with water in order to avoid raising dust. Every week or oftener the seats and confessional boxes are to be dusted with damp sponges and cloths. Every week or oftener the *grilles* of the confessional boxes are to be cleansed with alkaline lye and afterwards polished. The holy water fonts are to be emptied every week, or oftener if necessary, and washed either with boiling alkaline lye or with solution of corrosive sublimate (1 in 1000). Our readers will remember that THE LANCET of Jan. 27th, 1900, p. 252, contained a description of a new font for holy water devised by Mr. J. J. Bruns of Arnhem in Holland, and approved by the Archbishop of Utrecht. It is pleasing to find the clergy thus careful of the bodily as well as of the spiritual health of their people.

ON CERTAIN MENTAL AND NERVOUS DISTURBANCES DUE TO THE USE OF TRIONAL.

TRIONAL is now largely used as a hypnotic and cerebral sedative in various forms of nervous and mental ailments and thus the following case, which illustrates certain rare but important sequelæ following its use, has a special interest. Dr. Stuart Hart of New York refers to it in an article in the *American Journal of the Medical Sciences* for April. The case was that of a woman, aged 50 years, who for a period of 20 years was a sufferer from nervous depression, gastric dyspeptic troubles, and insomnia. She was apparently free from organic disease. For two months she had been taking trional at the rate of 15 grains every alternate day. At the end of that time (April 20th, 1899) she somewhat suddenly developed symptoms of acute gastro-intestinal irritation—viz., severe colicky pain, nausea, and vomiting. She was unable to retain food taken by the mouth, and only rectal feeding was possible. The trional was stopped and morphia was given hypodermically to allay the pain.

Hæmatoporphyrinuria next followed; a little albumin and a few granular casts appeared in the urine, and she began to suffer from cardiac disturbance and exhibited systolic and diastolic murmurs. The nervous disturbance took the form of peripheral neuritis leading to foot-drop and wrist-drop on the left side, and subsequently on the right side. These symptoms of extensor paralysis were preceded by tingling and pricking sensations about the vulva, the hands, and the feet The symptoms of hæmatolysis and renal disease above referred to were soon followed by those of cerebral toxæmia—viz., periods of delirium, mental confusion, and hallucinations of time and space. The pain in the extremities was complicated with pains and "girdle-sensations" in the abdomen which became severe. The skin generally was so hyperæsthetic that she could not tolerate the pressure of the bed-clothes. She lost flesh for the next few weeks, and had slight œdema of the ankles and considerable physical weakness. All these symptoms, however, gradually subsided and in the course of 12 months she quite recovered. The nervous troubles passed away in the order in which they appeared—viz., first the disturbances of the vagus and the heart, next the neuritis affecting the hand and foot on the left side, and lastly that of the hand and foot on the right side. The heart returned to the normal condition, leaving no trace of valvular disease or enlargement, and the mental condition was unimpaired, all traces of the hallucinations having completely passed away.

ASTRONOMY AT THE VATICAN.

IT is reported that an American citizen and a member of the Roman Catholic Church, who is much interested in celestial and terrestrial physics, has made what he calls a humble offering to the Pope in the shape of a telescope which is said to exceed greatly in size even the one shown at the Paris Exhibition of last year. His Holiness is stated to have accepted the gift, which is now destined to find a prominent place amongst the many valuable instruments of research of the Vatican Observatory which was presented just over a century ago by Cardinal Zelada with the then famous Dollond's telescope. In connexion with this statement it may be of interest to note that a very erroneous notion generally prevails with regard to the original development of the Vatican Observatory and that usually a quite recent date is assigned to it, though it would appear to be the oldest of its kind, with the exception, probably, of the one at Peking. It is true that the Vatican Observatory in its present outward appearance and constitution only dates back to 1888, the year in which Pope Leo XIII. celebrated the fiftieth anniversary of his priesthood. But there seems to be scarcely any doubt that an observatory tower was erected in Rome as far back as some time previous to 1582 and, as it would appear, chiefly in connexion with the reform of the Calendar. According to B. Crescenzi, the author of the important work which is entitled "Nautica Mediterranea," and which was published in Rome in 1607, Pope Gregory XIII. was mainly responsible for its erection It is recorded that the tower was intended exclusively for astronomical observations and researches, and there is, from an historical point of view, every reason to suppose that it was the first celestial watch-tower ever built in Rome. Since its erection, however, and partial endowment by Pope Gregory XIII., it passed through so many and so highly complicated vicissitudes that it now forms for the astronomical student a large and interesting field of historical speculation. We are, therefore, not surprised to observe that while it was at one time most anxiously cared for and the scientific work done there may be termed to have been of the utmost importance, at another time it was utterly neglected and devoid of any scientific management or control; finally, it became of world-wide renown at the beginning of the last century, chiefly on account of the scientific labours and able management of Philip Gill, who for a period extending over 30 years was its director. After the death, however, of Gill, which occurred in 1821, it again became quite disorganised. All the instruments and records were dispersed and the observatory itself was entirely deserted both as regards the scientific and social interests attached to it. In 1888 the Vatican Observatory commenced a new epoch in its history. In that year, as already mentioned, the commemoration of the fiftieth anniversary of the priesthood of Pope Leo XIII. took place, and on that occasion all the instruments and apparatus given by members of the Roman Catholic Church interested in celestial and terrestrial physics were brought together, and it then occurred to the organisers of the science section of the Vatican Exposition that they would find a suitable home in the old Gregorian tower. The suggestion was warmly approved and soon carried into effect and Father Denza, a great friend of Secchi, was now called upon to undertake the management of the revived observatory. He began his work in 1889 with a very interesting and varied programme which he and his able assistants have well carried out. The investigations which were thus introduced there relate to meteorology, terrestrial magnetism, astronomy, and lastly geodynamics. In addition, the building is well situated for meteorological researches and observations; moreover, it is well equipped with the most modern instruments necessary for the continuous record of meteorological data. Since 1889 it has always kept well apace with the times and would now bear comparison with any observatory in Europe.

OTITIS AND CEREBRO-SPINAL MENINGITIS.

MORE or less localised meningitis has long been a well-recognised sequel of otitis media, but diffuse affection of the cerebral and spinal meninges—cerebro-spinal meningitis—has not received much attention. At the meeting of the Société Médical des Hôpitaux of Paris on Feb. 1st M. Lermoyez reported two cases which showed that aural infection, even when slight, might give rise to cerebro-spinal meningitis by creating a means of entry for the meningococcus. More recently, at the meeting on March 8th, M. Vaquez and M. Ribierre described the following case. A woman, aged 37 years, entered hospital on Feb. 13th, 1901. Three weeks before, while in good health, she commenced to feel acute pains in the occipital region which for three or four days were without respite. Then the pains in the head diminished and pains in the lumbar spine, which radiated into the buttocks, the lower part of the abdomen, and the upper part of the thighs, appeared. Since June, 1900, she had had right purulent otitis which followed influenza. For several weeks there had been mental symptoms—depression amounting almost to melancholia, defective attention, and slight amnesia On admission the discharge was slight but very fœtid. The temperature was 104° F. and the pulse was 118. The occipital region was tender and was also the seat of spontaneous pains which constantly recurred. The patient had much difficulty in sitting up in bed and the movement aroused or increased the lumbar pains. Kernig's sign was well marked. Investigation of the knee-jerks was rendered difficult by flexor contracture. Intense delirium, the hydrocephalic cry, and rigidity of the neck followed. Lumbar puncture gave exit to pus containing a micrococcus which usually presented itself in the form of a diplococcus and took Gram's stain. Examination of the ear showed a polypus descending from the attic to the lower part of the middle ear. Death took place on Feb. 23rd. The necropsy showed some softening of the petrous portion of the right temporal bone and fibrino-purulent streaks on the anterior surface of the cerebellum and pons. The spinal canal was full of greenish-grey pus. Thus the meningitis was spinal more than cerebral. M. Vaquez and M. Ribierre drew attention to the non-severity of the aural condition and the absence of direct meningeal infection. They thought that the microbial invasion took place by the lymphatics and that instead of a local infection by contiguity a veritable sowing of the cerebro-spinal fluid with microbes took place.

THE REGISTRATION OF PLUMBERS.

A MEETING of representatives from various district councils throughout the United Kingdom and Ireland met some members of the Worshipful Company of Plumbers at the Guildhall on April 24th, when it was reported that some 2000 additional names had been added to the register within the past few months. The public will be well advised to welcome any measure that insures competency in those engaged upon the important work of the plumber, but the success of the movement rests more with the operative plumber than with the public. Unfortunately, until recently most of these men have regarded the aim at reform with indifference, because no immediate material gain appears likely to accrue to them from it. The Plumbers' Company, who have the best interests of the trade which they represent at heart, as well as a desire to benefit the public, have since the movement was inaugurated advanced a sum of no less than £25,000 to defray the excess of expenditure over income incurred in promoting the registration scheme, and the plumbers as a body should support them.

IMPROVEMENTS IN RADIOGRAPHY.

A DESCRIPTION of some recent improvements in radiographic apparatus was given not long ago by Dr. Rosenthal of Munich in an address delivered before the Munich Electro-technical Society. For the surgical localisation of foreign bodies, such as bullets embedded in the tissues, he had, in conjunction with Surgeon-General Professor von Angerer, devised an instrument called the "punktograph," which, he says, gives very accurate indications and can be used with the utmost facility. The punktograph consists of two rods having each a metallic ring at one end, and these rods are placed on opposite sides of the part of the body where the foreign object lies, in such positions that the latter, when viewed with the fluorescent screen, appears in the centre of both rings, and is therefore known to be in a line with them. The position of the rings being marked on the skin they are moved to other situations and the same process is repeated. The imaginary lines, the ends of which are thus marked on the skin, will obviously intersect in the foreign body, and its depth may be judged by a comparison of the distances between the two points forming each adjacent pair. With the help of apparatus manufactured by the Voltohm Electrical Company of Munich and Frankfort Dr. Rosenthal has, together with Professor Rieder, succeeded in taking photographs of the heart with an exposure of less than a second, and a number of such photographs will be inserted in a forthcoming work on the Roentgen rays in medicine by Professor von Ziemssen and Professor Rieder. All Roentgen ray images, whether photographs or views on the screen, are necessarily larger than the original object itself, because they are produced by the diverging rays from the focus tube. For examination of the heart, however, it is desirable to have the exact dimensions of the original, and this has been accomplished by the "orthodiagraph," devised by Professor Moritz of Munich and manufactured by the Voltohm Company. The illustration of the orthodiagraph shows a table on which the person to be examined presumably lies, and surrounding the table, near one end of it, is a rectangular moveable frame the plane of which is perpendicular. The focus tube is placed on the side of the frame which is underneath the table, and the principle involved seems to be the elimination of any error due to the divergency of the rays by moving the tube so that the outlines of the heart are traced out by rays which in all positions are parallel to a given direction.

THE NEW MEDICAL OFFICER OF HEALTH OF THE CITY OF LONDON.

DR. WILLIAM COLLINGRIDGE, the newly appointed medical officer of health of the City of London, was born in Islington in 1854 and was educated at Clewer House School, Windsor. In 1872 he entered as a student at St. Bartholomew's Hospital, and in 1875 he entered Christ's College, Cambridge, where he took the degrees of M.A., M.B., D.P.H., and M.D., and subsequently that of LL.M. During the Turco-Servian war in 1876 Dr. Collingridge went to Belgrade as a volunteer surgeon and was the first English surgeon to arrive. He immediately received a commission as surgeon and left for the army before Novi-Bazar, where he engaged in hospital organisation. At the end of the war Dr. Collingridge was decorated by King Milan with the order of the Takova, and on his return home was appointed medical officer of the Port of London. In this capacity he has been engaged for the past 20 years. In 1892 he was appointed as surgeon-major to the command of an experimental company of the new Militia Medical Staff Corps. This company proving successful, the corps was enlarged to eight companies, and subsequently Dr. Collingridge was appointed surgeon-lieutenant-colonel commanding, a post from which he retired in 1900. Dr. Collingridge is an Honorary Associate of the Order of St. John of Jerusalem.

THE LONDON PSYCHO-THERAPEUTIC SOCIETY.

WE have received a circular informing us that at a meeting of medical men and others interested in the study and application of psycho-magnetics, mesmerism, hypnotism, and kindred psychic and mental forces, held at the Frascati Restaurant, London, on April 1st last, it was unanimously decided to establish an organisation under the title of the London Psycho-Therapeutic Society. The society has in view, amongst other objects, the systematic study and investigation of the psychic and mental forces upon such lines as may be considered desirable, and it is hoped to establish central headquarters where the poor may be freed from those diseases especially susceptible to psychic and mental treatment. The society does not propose to be in any way antagonistic to existing scientific and sectarian bodies interested in these subtle forces. Rather it is desired to draw into one society representatives of all the various schools of thought. This is a catholic basis with a vengeance and we cannot help thinking that the gentleman responsible for the first meeting having been held on April 1st was singularly happy in his choice of a date. The idea of medical men, or of any other body of men capable of exercising common sense, meeting on a common platform with the so-called Christian Scientists, with the exponents of the Viavi system, or with osteopathists is too ridiculous for words. We are not unwilling to allow that treatment by hypnotic suggestion may have a certain value when carried out by an honest and properly trained medical man and our review of Dr. Lloyd Tuckey's work upon the subject[1] is a proof of what we say. The debate upon hypnotism at the Edinburgh meeting of the British Medical Association[2] shows that medical men are willing and anxious to study the matter in a scientific manner and we cannot see that another society whose constitution would evidently open the door to fraud of various kinds is necessary.

---

[1] THE LANCET, Nov. 3rd, 1900, p. 1279.

THE STEAMBOAT SERVICES ON THE THAMES.

IT is to be wished that the excellent efforts of the Thames Steamboat Company to place the great river highway at the disposal of the public as a means of getting from place to place will be crowned with success. There can be no doubt that travelling by waterway is healthful, and certainly more so than travelling *sub terra*. The air over the river is always fresh, the constant contact of a breeze with the water in motion tending to keep up a maximum degree of organic purity The prospects of a successful service seem this year to be bright, and a very good start has been made. On May Day a review of the fleet of the company's steamers was held and crowds witnessed the lively and somewhat novel scene from the Thames Embankment. The fleet consists of 36 steamers and it is proposed to run a rapid service of boats between London Bridge and Battersea, while boats will run also to Greenwich and Woolwich, to Kew Gardens, and to Hampton Court. It seems an anachronism that the Thames is not yet a popular or successful waterway, although there is no doubt that a good service of steamers would be a source of convenience to thousands. The whole project is, however, heavily handicapped by the excessive tolls levied at the piers. These tolls should be abolished in the interests of a very large section of the metropolitan public. Such an imposition is fatal to the development of the enterprise and a hindrance to the improvement of the steamers. On every other navigable river of the civilised world the excellence of the appointments of the passenger steamers and the excellence also of their construction and design are well known. The greatest city in the world still leaves much to be desired in regard to its steamboat services on its great historic waterway

STREET NOISES.

SOME little time ago the London County Council passed a by-law to the effect that no one should shout to the annoyance of the public while hawking newspapers. This order was promptly backed by the issue of a circular from the Commissioner of Police stating that the police were instructed to see that the by-law was obeyed During the winter, when there was little or no racing, the streets were fairly quiet, but with the commencement of the flat-racing season the ears of workers are again assailed from the hour of seven o'clock in the morning with the yells of sellers of race cards and newspapers giving racing results or "runners and betting." The police take absolutely no notice. A brain-worker appealed recently to a constable in the Strand and was told that if he pointed out any specific offender the man would be charged at the police court if the complainant was prepared to appear and to give evidence. Now such a method of procedure entirely destroys the value of the by-law. It is not to be expected that, say a literary man or a banker, can leave whatever work he is engaged in, run down sundry flights of stairs as soon as he hears a winner yeller, find a policeman, and, if the yeller has not run away, point him out, ascertain when he will be charged, and again leave his work to go to give evidence. Some little time ago a policeman arrested on his own initiative a newspaper hawker for shouting and the magistrate, Mr. Plowden, inflicted a fine.[3] We cannot see why this procedure should not be universally followed. As we have said over and over again there is no need to shout. The sellers of matches and penny toys do not as a rule shout, nor do the sellers of many newspapers, and it is monstrous that "Winners" and the like should be yelled by hawkers to the unspeakable annoyance of those who have to work with their brains. A few arrests by the police emphasised by a protest signed by dwellers and toilers in our busy thoroughfares would do an immense amount of good.

THE DUTIES OF A MEDICAL OFFICER OF HEALTH.

AS we have so often said, the duties of a medical officer of health are, if properly performed, sure to bring him into conflict with somebody sooner or later. A good instance of this is seen in an incident which occurred at a recent meeting of the Lancaster District Council. Mr. G. R. Parker had in his report to the Health Committee called attention to certain conditions existing at Cockerham Hill Farm of which a gentleman named Colonel Bird is apparently the landlord. According to the *Lancaster Guardian* of April 27th, Mr. Langley, the inspector of nuisances, said that "the statements which Dr Parker had made were quite correct." Colonel Bird, however, characterised Mr. Parker's statements as "absurd, untrue, and incorrect." He also accused him of getting information from "some person who was not connected with the farm" and of making a report upon "what he might call hearsay evidence." Eventually Colonel Bird suggested that the farm should be inspected by members of the council, and this was agreed to We are glad to see that the *Lancaster Guardian* points out that the chairman of the meeting should have made a firmer stand. We have no wish to imply that medical officers of health are always infallible, but it is a scandal that an interested person should be allowed to attack a public official merely for doing his duty. We do not, of course, know how soon after the meeting the members of the council were to examine the farm In any case they will probably find that the grosser evils will have been remedied, but we trust that Colonel Bird will be made to understand that a medical officer of health acts for the benefit of the community and not for that of any one member of it, and, in addition, that for an accused person to defend himself it is not necessary to charge the accuser with lying.

ECHINOCOCCUS CYSTS OF THE DORSAL MUSCLES.

IN the *Gazzetta degli Ospedali e delle Cliniche* of April 21st Dr. Alfredo Baldacci of Pisa gives a lengthy account of a case of this rare condition. The patient was a married woman resident in Pisa and 31 years of age About four years ago she noticed a roundish swelling of the size of a pigeon's egg on her left side in the axillary region in the fifth or sixth intercostal space. It increased in size and in two years was as large as a fowl's egg. After a fall downstairs, in which she bruised her shoulder, the swelling increased more rapidly and in about a month it was of the size of a large apple. On March 5th, 1900, she was admitted into hospital, where the swelling was diagnosed as a chronic abscess (*ascesso freddo*) under the left axilla; 17 ounces of purulent fluid were withdrawn by means of Dieulafoy's aspirator and the patient was discharged on March 25th. The swelling soon returned and a second one made its appearance close beside the first; the patient was re-admitted to hospital on Feb 4th, 1901, and the case was again diagnosed as one of subaxillary chronic abscesses probably due to caries of a rib. On Feb 6th aspiration with Dieulafoy's instrument was again resorted to, but with only partial success, for after 21 ounces of thick purulent fluid were withdrawn the flow ceased entirely, although the swelling remained of considerable size. On Feb. 10th a free incision was made under chloroform and four separate cysts were found. One was of the size of the head of a fœtus at the sixth month and lay between the trapezius, the latissimus dorsi, and the serratus magnus; one, of the size of an apple, lay in the thickness of the trapezius; one, somewhat smaller than the last-mentioned, was between the latissimus dorsi and the lumbo-dorsal aponeurosis; and the fourth, of the size of an egg, was in contact with the intercostal muscles.

[3] THE LANCET, July 14th, 1900, p. 120.

THE FATAL GLOVE FIGHT AT THE NATIONAL SPORTING CLUB.

At the inquest held to inquire into the circumstances attending the death of Murray Livingstone, professionally known as "Billy Smith," which was concluded before Mr. John Troutbeck on Monday last, the jury returned a verdict of "Accidental death." The cause of death was proved by a post-mortem examination to be the rupture of one of the cerebral vessels. Every precaution seems to have been taken by the promoters of the competition against accident, the fight was perfectly fair, and both men were properly trained. Accident was the only possible verdict. To quote the words of a witness: "So long as boxing matches are legal there will be accidents," and we can but agree in this opinion. We believe that this is the fourth death which has occurred after boxing competitions at the National Sporting Club since its inception 10 years ago. The curious fact is, that deaths should occur at an institution where every possible care is taken to provide against mishap, whereas boxing competitions take place nightly on brick-paved floors in the roughest environment and no harm occurs. It seems to be simply bad luck that the inevitable toll of lives exacted by a sport of enormously widespread popularity should be exacted in the very place where all precautions are taken.

Dr. Robert Hutchison will give a special course on Foods and Dietetics during the Summer Session, at the London Hospital Medical College. The lectures will be delivered on Wednesdays and Fridays, commencing on Wednesday, May 8th, in the Physiological Theatre. The fee for the course to others than students of the college will be £2 2*s.* and further particulars will be given by Mr. M. Scott, the Warden.

The Medical Society of London will hold a conversazione in the rooms of the society, 11, Chandos-street, Cavendish-square, on Monday, May 20th. Mr. F. Richardson Cross, F.R.C.S., will deliver the Oration, on "Some Landmarks in the Progress of Medical Science," at 8.45 P.M. Previously there will be a reception by the President and subsequently smoking will be permitted to the accompaniment of the "Bijou" Orchestra.

The Committee of Inquiry appointed by the Governors of the National Hospital for the Paralysed and Epileptic held their first meeting on Wednesday last. The committee is constituted as follows: Sir Edward Fry (chairman), Lord Wolverton, Sir W. W. Karslake, Mr. Timothy Holmes, F.R.C.S. and Mr. Cecil Russell, with Mr. J. Danvers Power as honorary secretary. The business of the meeting was of a purely formal character.

An inquest was held last week at Poplar upon the body of a man when a verdict was returned of "Death from lead-poisoning." The medical evidence showed that the man died from intestinal obstruction, presumably of malignant origin. A question will be asked about the matter in the House of Commons, we hear as we go to press, when the public will be placed in possession of the real facts.

Under the presidency of Sir William Broadbent the friends and members of the Medical Graduates' College and Polyclinic held a conversazione on May 1st, at 22, Chenies-street. There was a good attendance, the chief attraction being an interesting lecture by Mr. Jonathan Hutchinson on (*a*) the Retention of the Leaf in Deciduous Trees, and (*b*) the Suppression of the Tusk in Elephants.

The annual meeting and May dinner of the Aberdeen University Club, London, will be held at the Trocadéro Restaurant on Wednesday, May 15th, at 7 P.M. The chair will be taken by Dr J. Mitchell Bruce, and those intending to be present should communicate with the honorary secretaries, Dr. James Galloway and Mr. J. A. Robson, at 54, Harley-street, W.

A telegram from Sir W. F. Hely Hutchinson, the Governor of the Cape of Good Hope, to Mr. Chamberlain, received at the Colonial Office on April 25th, states that for the week ending April 20th there were 64 cases of plague admitted, of which number 17 were Europeans. No fresh cases had occurred among persons under military and naval control.

The Ingleby Lecture of the University of Birmingham will be delivered on Tuesday, May 14th, at 4 o'clock, in the medical lecture theatre of the University, by Dr. William J. Smyly, President of the Glasgow Obstetrical and Gynæcological Society, who has taken for his subject "The Lower Uterine Segment and the Contraction Ring."

The annual dinner of the West London Medico-Chirurgical Society will be held at Frascati's Restaurant, Oxford-street, W., on Wednesday, May 8th, at 7.30 P.M. Further particulars can be obtained from the secretary, Dr. G. P. Shuter, Chiswick-lane, W.

His Majesty the King has graciously consented to become patron of the Middlesex Hospital, a position which Her late Majesty Queen Victoria as well as her predecessors George IV. and William IV. held during the whole of their reigns.

At a meeting of Grand Lodge of English Freemasons held on April 24th at Freemasons' Hall, Bro. Francis Woodhouse Braine, F.R.C.S., was appointed and invested as one of the Senior Grand Deacons.

Queen Alexandra has graciously consented to continue her patronage of the West-End Hospital for Nervous Diseases, Epilepsy, and Paralysis, Welbeck-street, Cavendish-square, W.

The death is announced as having occurred suddenly in London of Dr. John Cavafy, for many years physician to St. George's Hospital.

THE BATTLE OF THE CLUBS.

Lay Medical Institutions.

Dr. Leslie Phillips has addressed a memorial to the General Medical Council pointing out the anomalous position in which medical men stand who are attached to institutions giving medical advice which are either owned or governed by laymen. Shortly, Dr. Phillips's argument is as follows. The Medical Acts of 1858 and 1886 provide that only registered medical men can recover charges for medical services at law. Many institutions are owned by laymen and give medical advice by means of a medical man who is a paid servant. If the patients of these institutions did not pay in advance the proprietors would lose their money, for they themselves could not sue, being unqualified, and if the medical man were to sue the patients would deny that they had ever contracted with him. For laymen to carry on a medical practice in this way is illegal, therefore any medical man who assists in the carrying on of such a practice is acting "not only against the spirit but against the letter of the law." Pay hospitals stand in the same category as medical aid associations. Dr. Phillips implores the General Medical Council to make the holding of such posts as he describes conduct "infamous in a professional respect." Dr. Phillips's view does not seem to us to be *legally sound. Firstly, anybody may practise so long as he* does not give himself out to be a medical man. Secondly, there is nothing illegal in any layman, or combination of laymen, keeping a medical man as their paid servant. The surgeon to a large works or a colliery is in exactly the same position *legally* as are the medical men who were in the service of Mr. Y. and Mr. Z., or of the friendly societies who were referred to in THE LANCET of Jan. 4th, 1898 The illegality theory will never do, and the only method, so far as we can see, of doing away with institutions of the kind mentioned by Dr. Phillips is to make it plain, first, to medical men that it is not nice to be sweated, and second, to patients that it is not for their benefit that they should be attended by an overworked practitioner.

CONTRACT PRACTICE MIDWIFERY FEES.

The Midland Medical Union is at present occupied with the following case. Dr. W. C Rainsbury is surgeon to the Stanton Hill Colliery Club. The contract is for medical and surgical attendance, not including midwifery, and the fee in the past for midwifery has been half a guinea. A few months ago Dr. Rainsbury, in accordance with a resolution of the Midland Medical Union, raised his fee for midwifery to one guinea. After a great deal of discussion and after meetings had been held between the representatives of the colliery club on the one hand and Dr. Rainsbury and the members of the Midland Medical Union on the other, the club refused to give way and Dr. Rainsbury received three months' notice to terminate his appointment as *surgeon to the club. The union is supporting Dr.* Rainsbury in his demand, but at present the wives of colliers are attended by practitioners who are not members of the Midland Medical Union for half a guinea. There is no doubt, in our opinion, that a collier is perfectly well able to pay a guinea as a midwifery fee. The wages of colliers are very good in addition to the fact that they get coal for next to nothing, instead of having to pay 30*s*. or more per ton as others have to do. It is advisable that any medical man who is thinking of applying for this or any other contract appointment in Nottinghamshire or in Derbyshire should before doing so communicate with the secretaries of the Midland Medical Union, Dr. Ernest Houfton, Shirebrook, near Mansfield, or Mr. C. J. Palmer, Mansfield-Woodhouse.

SHIP-BORNE RATS AND PLAGUE.

A MEMORANDUM has been prepared by the medical officer of the Local Government Board with regard to the risk of importing plague into this country by means of plague-infected rats on board ships. In it the steps are detailed which, in the opinion of the Board, should be taken by sanitary authorities of seaports with the view of preventing the introduction of the disease in this way. The Board request that sanitary authorities will instruct their officers to use their best efforts to secure the carrying into effect of the suggestions which the memorandum contains and recommend that a copy of the memorandum should be given to the medical officer of health and another to the inspector of nuisances.

[OFFICIAL COPY]

SHIP-BORNE RATS AND PLAGUE.

In view of the susceptibility of the rat to plague, and of risk therefore [illegible] fected [illegible] event [illegible] oyage [illegible] asures [illegible] d the [illegible] event [illegible] from [illegible] s and hawsers in use for mooring purposes.

2. In the case of vessels that have come from places infected with plague, but on board of which no plague or suspected plague has occurred, strict inquiry should be made on their arrival in port as to [illegible] should be viewed with suspicion and as giving occasion for action similar to that indicated under Paragraph 2.

4 Rats when destroyed on shipboard should not be handled; they should be at once cremated

5. [illegible] being *found to be infected* [illegible] by those animals should, [illegible] vaded by plague should endeavour to secure the destruction of the rats of the town, not least [illegible] warehouses Measures should [illegible] their way on board vessels [illegible] roy all rats on board ships [illegible] of such vessels should be urged to take steps during the ensuing voyage for the destruction of rats that may have remained alive on board their vessels notwithstanding the action of the local authority.

W. H. POWER, Medical Officer.

Local Government Board, Medical Department, April, 1901.

THE ROYAL ACADEMY.

THE Exhibition of the Royal Academy of Arts, which will open to the public on May 7th, gives the visitor the impression that bad times, the war, and the general depression have affected artists, for this exhibition is curiously dull. There are, however, not so many pictures dealing with the war or with the last days of Her Majesty the late Queen as might have been expected. M. Benjamin Constant's picture of the Queen (149) occupies the wall at the end of Gallery No. III., being surrounded by drapery of blue and crêpe. She is sitting in a chair of state in a Gothic chamber, presumably the House of Lords, with a curiously stagy effect of light falling across her. Mr. Wyllie in "The Passing of a Great Queen" (272) shows the little *Victoria and Albert* with her escort of torpedo boats passing down the Solent through the sentinel lines of warships. In the sculpture room is a model (1711) of a memorial to the late Queen to be erected in Manchester. In its present situation it looks, of course, much too big.

The most impressive work in the exhibition is Mr. Sargent's portrait of the two Misses Wertheimer. The one is dressed in crimson velvet and the other in white satin. The picture is so far above any other in the whole exhibition, even including other works by the same artist, that we need say no more than that it is a worthy companion to the portrait of the ladies' father which Mr. Sargent exhibited in 1898 Of medical portraits, that of Dr P. H. Pye-Smith (525), by Mr. H. J. Draper, should be noticed both as an admirable likeness and a clever study of blacks. In the Lecture Room is a bust (1733) of Dr. Isambard Owen by Mr. W Goscombe John, and a medal by Mr. C. J. Allen, the obverse of the Kanthack memorial medal (1746). This is a departure from the ordinary form of medal in that the head and inscription are within a vesica. Mr. Thomas Brock shows the presentation bust of the late Mr. Henry Lee, F R.C S, which is to be placed in the Royal College of Surgeons of England. Of figure pictures the "Venusberg" (794), by the Hon. John Collier, and "When Land and Water Kiss" (845), by Mr. H. J Draper show a good knowledge of anatomical drawing and modelling. To pass to other pictures Mr. La Thangue's landscapes are, *as always, a pleasure to the eye especially.* "On Lavington Down" (22), Mr. Waterhouse's "Mermaid" (138) a diploma work, and "Nymphs finding the Head of Orpheus" (231), are good examples of beautiful colour. Mr. Byam Shaw in "The Boer War" (241) has deserted his usual mediæval mysticism and shown us a modern woman standing by a stream. The wealth of detail in the willows, foxgloves, and loosestrife recalls to some extent the "Ophelia" of Millais. Of other landscapes we must mention (638) a view of "Bellagio from Cadenabbia," by Sir Henry Thompson, F.R C S., who has deserted his usual *medium of water-colour for that of oil.* Mr Ridley Corbet has a charming view of the Val d'Arno (863), and Mr. Albert Goodwin, besides his "Rye" (983), has a beautiful fantasy, "Sindbad the Sailor in the Harbour of Salahut" (784), and his two other pictures (53 and 438), which like all this master's work, should by no means be passed over. We must not forget Mr. Melton Fisher's "Lady

Welby" (367), which is characterised by all his delicacy of handling, and among the sculpture Mr. J. M. Swan's bronze group, "Puma and Macaw," is a wonderful example of stealthy motion.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary meeting of the Comitia was held on April 25th, Sir William Selby Church, the President, being in the chair.

The following gentlemen, having passed the required examination, were balloted for, and having been elected were admitted as Members:—Francis Robert Bryant Bisshopp, M.A., M.D. Camb.; Frank Cecil Eve, B.A., M.B. Camb.; Archibald Gordon Gullan, M.D. Lond., L.R.C.P.; Edward Forster Maynard, M.D. Edin.; Nathan Raw, M.D. Durh.; Charles Henry Reissmann, M.A., M.B. Camb., L.R.C.P.; and Reginald Cecil Bligh Wall, B.A., M.B. Oxon., L.R.C.P.

Licences to practise were granted to 96 gentlemen who had passed the necessary examinations.

A communication was received from the Secretary of the Royal College of Surgeons of England reporting certain proceedings of the Council on April 11th.

The following Members were nominated by the Council and proposed to the College for election to the Fellowship, and after a ballot had been taken were all duly announced to have been elected: William Burns Beatson, M.D. St. And. (Eastbourne); Arthur Hamilton Nicholson Lewers, M.D. Lond.; John Walter Carr, M.D. Lond.; William Joseph Tyson, M.D. Durh. (Folkestone); Edmund Hobhouse, M.D. Oxon. (Brighton); William Rivers Pollock, M.D. Camb.; Hugh Walsham, M.D. Camb.; Walter Sydney Lazarus-Barlow, M.D. Camb.; Edmond Fauriel Trevelyan, M.D. Lond. (Leeds); John Hannah Drysdale, M.D. Camb.; Frederick Eustace Batten, M.D. Camb.; Raymond Henry Payne Crawfurd, M.D. Oxon.; John Henry Bryant, M.D. Lond.; and George Frederic Still, M.D. Camb.

A report, dated March 11th, was received from the Committee of Management. Amongst other matters the announcement was made that the Blackburn Technical College had been added to the list of institutions recognised for instruction in chemistry, physics, and practical chemistry.

A report was received, dated March 8th, from the Laboratories Committee recording the general work of the laboratories and of the bacteriological department, and announcing that Dr. T. Grigor Brodie had been appointed director of the laboratories for another year. The report was adopted.

The quarterly reports of the Finance Committee and of the examiners for the licence were received and adopted.

The Registrar moved that By-law CXLV. be amended in the manner of which notice had been given at the preceding Comitia. This was carried.

A list of books and other publications which had been presented to the library during the past quarter was received and the thanks of the College were given to the donors.

It was announced that the subject of the Bradshaw lecture to be delivered by Dr. Judson Bury would be "Prognosis in Relation to Disease of the Nervous System."

The President then dissolved the Comitia.

Church Missionary Society.—The annual meeting of the friends of the medical mission auxiliary of this society was held at Exeter Hall, London, on April 30th, when Sir John Kennaway presided. Dr. Herbert H. Lankester, the secretary, reported that during the year the beds in the society's hospitals had increased from 1484 to 1613; the in-patients from 11,400 to 11,887; and the out-patients from 630,000 to 753,000. A medical training home for ladies had this year been opened in Bermondsey. The income of the auxiliary had risen from £10,600 to £12,930, besides £2737 brought forward and £3797 from the Centenary Fund. The expenditure had been £17,962, but the debit balance was only £484. The committee had undertaken to maintain all the society's medical missionaries, and this would mean an increase of £5000 a year in financial liability.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Cambridge Urban District.—An outbreak of diphtheria occurred in this and the adjoining district of Chesterton during the autumn of 1900, and although there was nothing of an exceptional character about the outbreak certain of the methods adopted with a view to control it were conceived and carried out in a commendably modern spirit. The outbreak, which embraced 62 cases and which was mainly connected with the Park-street Infant School, commenced on Oct. 14th and lasted until Nov. 15th. With respect, however, to the precise number of cases Dr. Bushell Anningson, the medical officer of health, observes that some cases were notified on clinical symptoms alone, notwithstanding the fact that the specific bacillus was not found in the throat, while others were notified upon the discovery of the specific bacillus alone even if no clinical symptoms were present. In other cases, however, the diagnosis was supported both clinically and bacteriologically. Evidence as to the precise cause of the outbreak is not forthcoming, but a thesis of unrecognised cases operating in a school affords a substantial solution of the difficulty. Moreover, the sanitary condition of the closets and urinals was unsatisfactory and may have brought about a state of the fauces susceptible to the operations of the bacillus of diphtheria. As regards preventive measures, Professor Sims Woodhead was appointed consulting bacteriologist, and the invaded school was closed. Isolation accommodation was provided separately both for cases of actual diphtheria and for cases in which the bacilli of the disease alone had been found. Moreover—and here we have the up-to-date nature of the prophylactic measures—the infants who had been attending the invaded school were visited at their homes, a bacteriological examination was made in each case, and a prophylactic injection of antitoxin was offered not only to the infants but also to their younger brothers and sisters. It is of considerable interest to learn that the offer was, as a rule, accepted, and such acceptance does great credit to the tact of those whose duty it was to make the offer. But the liberality of the Cambridge Corporation did not stop here, as the medical practitioners of the borough were afforded a gratuitous supply of antitoxin and facilities for obtaining a bacteriological examination of any suspicious cases under their care. Good results appear to have followed the use of antitoxin in the case of children who had attended the invaded schools, and consequently the corporation instituted a public injecting station at the Corn Exchange whereat all parents whose children had been exposed to infection were at liberty to have them treated with antitoxin free of charge. As regards the bacteriological aspects of the outbreak, Dr. Anningson reports that a total of 650 persons had their throats examined, and of this number 33 yielded the bacillus of the first degree of virulence and 157 that of the second degree. The remainder gave negative results. Dr. Anningson is to be cordially congratulated upon the comprehensive and modern measures which were taken in Cambridge to stay the outbreak, and it is clear, as indeed he fully recognises, that all the parties concerned must have worked with a remarkable unanimity.

Middlesbrough Urban District.—This borough has for the last five years suffered severely from pneumonia of a definitely infective type and it will be remembered that Middlesbrough was the scene of the historical outbreak of epidemic pneumonia which took place in 1888 and which was investigated by Ballard and Klein. At that time there were 388 deaths. Klein found a bacillus which he called "bacillus pneumoniæ," the inoculation of which into mice gave rise to a disease in which pneumonia was a very prominent symptom. This same bacillus was found in certain samples of bacon, and mice fed thereon developed pneumonia and yielded the bacillus pneumoniæ. During 1900—the estimated population being 97,007—there were no less than 543 deaths from pneumonia, the annual numbers since 1896 having been 275, 265, 225, and 397. It has, however, to be remarked as having a bearing upon the figures for 1900 that in May of that year the Town

Council made pneumonia a voluntarily notifiable disease, although it appears that the stress of the 1900 outbreak was over before notification commenced. The number of cases notified since May was 187—i.e., 138 males and 49 females. Of the total of 187 no less than 71 died—a fatality rate of 37·9—which was much in excess of that which obtained in 1888. As in 1888, males were more liable to attack than females. The bacteriological portion of the investigation was performed by Mr. Alexander Foulerton, who was unable to discover the presence of the diplococcus pneumoniæ in any of the cases, but he is inclined to regard an organism which he names "Middlesbrough bacillus No. 2" as having played an important part in the outbreak. In the words of Mr. Foulerton, "this 'Middlesbrough bacillus No. 2' proved to be identical in every way with what is *recognised as bacillus coli communis* and appeared to be quite normal in type." With regard to the bacteriological aspect of the question, Dr. Charles V. Dingle, the medical officer of health of Middlesbrough, observes: "The results obtained cannot be said to be conclusive proof that the above bacillus is the only cause of the excessive pneumonia met with in this borough, and it is hoped that further and more conclusive evidence will be obtained in future." As matters stand the bacteriology of epidemic pneumonia must be regarded as being in a somewhat evolutionary phase. As far as we can gather the results of Mr. Foulerton's investigations agree with Klein's in that in no case was Friedländer's or Fränkel's pneumococcus discovered, but we are not told whether "Middlesbrough bacillus No. 2" is claimed to be identical with Klein's bacillus pneumoniæ.

Stoke-upon-Trent Urban District.—Dr. G. Petgrave Johnson reports that during 1900 there were two deaths in this district from the consumption of veal. This meat, procured *on a certain Saturday, was stuffed with herb and eaten* hot on the following Sunday at the midday meal. At supper on the same day nine persons partook of the cold meat and one additional person abstained. The next day seven of the nine veal-eaters were attacked with vomiting, diarrhœa, and abdominal pains. On the evening of the same day a visitor had a piece of the same cold veal and was ill on the day following. The history of the veal was inquired into and it appears that none of the other eaters of meat from the same calf were taken ill. Dr. Johnson thinks that the meat was contaminated after it had been cooked, seeing that those who ate the hot meat were not attacked. It does not seem that any bacteriological or inoculation experiments were made, and this, under the circumstances, is to be regretted. Cases of this nature, investigated in a bacteriological sense quite early, are likely to lead to instructive results, as has been shown by Durham and others. The borough of Stoke-upon-Trent is without a disinfecting apparatus, and therefore, as the medical officer of health remarks, it has been impossible to disinfect any infected clothing or bedding. In 1886 Dr. Barry of the Local Government Board advised such an apparatus, and the medical officer of health has frequently reported in the same strain, but the district council has remained obdurate

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6671 births and 4047 deaths were registered during the week ending April 27th. The annual rate of mortality in these towns, which had been 19·2, 19·2, and 18·4 per 1000 in the three preceding weeks, further declined to 17·9 per 1000 last week. In London the death-rate was 17·4 per 1000, while it averaged 18·2 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 10·3 in West Ham, 11·4 in Derby, 11·7 in Brighton, and 11·8 in Birkenhead; the highest rates were 22·8 in Liverpool, 24·4 in Halifax, 24·8 in Bolton, and 26·1 in Plymouth. The 4047 deaths in these towns included 363 which were referred to the principal zymotic diseases, against 397 and 346 in the two preceding weeks; of these, 122 resulted from whooping-cough, 101 from measles, 48 from diphtheria, 36 from diarrhœal diseases, 30 from scarlet fever, and 26 from "fever" (principally enteric). No death from any of these diseases was registered last week in Burnley; in the other towns they caused the lowest death-rates in Croydon, Plymouth, Norwich, Derby, Birkenhead, and Huddersfield, and the highest rates in Bolton, Salford, Blackburn, and Sunderland. The greatest mortality from measles occurred in Wolverhampton, Bolton, Sunderland, and Gateshead; from scarlet fever in Preston; from whooping-cough in Bristol, Cardiff, Swansea, Bradford, and Sunderland; and from "fever" in Blackburn and Sunderland. The 48 deaths from diphtheria included 20 in London, four in Salford, four in Leeds, and three in Liverpool. No fatal case of small-pox was registered in any of the 33 large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums hospitals during last week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1522, against 1601 and 1526 on the two preceding Saturdays; 198 new cases were admitted during the week, against 160, 205, and 150 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 345 and 374 in the two preceding weeks, decreased again last week to 286, and were 71 below the corrected average. The causes of 46, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Norwich, Nottingham, Salford, Bradford, and seven other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·1, 23·2, and 23·0 per 1000 in the three preceding weeks, further declined to 22·9 per 1000 during the week ending April 27th, but showed an excess of 5·0 per 1000 over the mean rate during the same period in the 33 large English towns. *The rates in the eight Scotch towns* ranged from 11·8 in Perth and 18·8 in Dundee to 23·7 in Glasgow and 24·5 in Edinburgh. The 717 deaths in these towns included 62 which were referred to whooping-cough, 25 to measles, 13 to diarrhœa, eight to scarlet fever, five to "fever," four to diphtheria, and three to small-pox. In all, 120 deaths resulted from these principal zymotic diseases last week, against 95 and 117 in the two preceding weeks. These 120 deaths were equal to an annual rate of 3·8 per 1000, which was 2·2 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 51 and 56 in the two preceding weeks, further rose last week to 62, of which 34 occurred in Glasgow, 18 in Edinburgh, five in Dundee, and four in Paisley. The deaths from measles, which had been 16, 17, and 21 in the three preceding weeks, further rose to 25 last week, and included seven in Glasgow, seven in Leith, six in Edinburgh, three in Paisley, and two in Greenock. The fatal cases of diarrhœa, which had been eight, 13, and 23 in the three preceding weeks, declined again last week to 13, of which seven were registered in Glasgow, three in Dundee, and two in Aberdeen. The deaths from scarlet fever, which had been three and two in the two preceding weeks, rose again to eight last week, and included four in Glasgow. *The fatal cases of "fever," which had* been one and four in the two preceding weeks, further rose last week to five, of which three occurred in Glasgow, where two of the four deaths from diphtheria were also registered. The fatal cases of small pox, which had been five, six, and 10 in the three preceding weeks, declined again last week to three, and all occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 155 and 130 in the two preceding weeks, rose again last week to 179, and showed an excess of 38 over the number in the corresponding period of last year. The causes of 36, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 35·6 and 35·4 per 1000 in the two preceding weeks, further declined to 29·4 during the week ending April 27th. During the past four weeks the death-rate in the city has averaged 33·1 per 1000, the rates during the same period being 17·7 in London and 23·2 in Edinburgh. The 195 deaths of persons belonging to Dublin registered during the week under notice were 40 less than the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 12, 15, and 18 in the three preceding weeks; of these, eight resulted from whooping-cough, one from scarlet fever, and one from "fever." These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·6 in London and 4·4 in Edinburgh. The fatal cases of whooping-cough, which had been five, eight, and nine in the three preceding weeks, declined again last week to eight. The mortality both from scarlet fever and from "fever" showed a decline from that recorded in the preceding week. The 195 deaths in Dublin last week included 27 of children under one year of age and 56 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decrease from the respective numbers registered in the preceding week. Six inquest cases and four deaths from violence were registered; and 61, or nearly one-third, of the deaths occurred in public institutions. The causes of six, or more than 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon W. E. Breton to the *President* for a three months' course of hospital study. Staff Surgeons: V. G. Thorpe, to the *Centurion* for service with the Marines at Wei-hai-wei, and P E. Maitland to the *Argonaut*. Surgeons: J G. Corry to the *Niobe;* J. W. Craig to the *Northampton* for the *Calliope*; T. W Kemp to Bermuda Hospital; E. O. B. Carbery to the *Jackal;* W. R. Knightley to the *Duke of Wellington*, for disposal; J. H. Fergusson to the *Harrier;* A. G. W Bowen to the *Beagle;* H. E. Tomlinson to the Plymouth Division, R.M.L.I, and Civil Practitioner W. Martin to be Surgeon and Agent at Port Muck.

ROYAL ARMY MEDICAL CORPS.

Major G. Brazier-Creagh joins at Woolwich. Major A. M. Davies is ordered to join the Home District for duty. Major A. Dodd has joined at Aldershot for duty at the Cambridge Hospital. Captain H. A. Stalkartt is appointed for duty in the Scottish district.

The undermentioned Lieutenant-Colonels, whose promotions were notified in the *London Gazette* of March 29th, 1901, take precedence next below Lieutenant-Colonel W. C. T. Poole: Richard Edward Ricketts Morse, Richard Henry Stewart Sawyer, and Richard Charles Kirby Laffan.

Lieutenant-Colonel Arthur Bowdich Cottell retires on retired pay. Colonel Charles Fleetwood Churchill is placed on retired pay. Lieutenant-Colonel Robert Talbot Beamish is placed on retired pay.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain W. K. Bullmore having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Lieutenant Herbert Fox, 2nd Hampshire Volunteer Artillery, to be Surgeon-Lieutenant.

INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the following promotions among the officers of the Indian Medical Service:—Lieutenants to be Captains: Thomas Henry Delany, John Walter Forbes Rait, Stewart Ranken Douglas, Eugene John O'Meara, Godfrey Tate, Roy Fearon Baird, Andrew Thomas Gage, George Campbell Laing, George McPherson, Spencer Hunt, Alfred George Sargent, Walter Hulbert Cox, De Vere Condon, Henry Albert John Gidney, Henry Kirkpatrick, Frederick Durand Stirling Fayrer, Padmabar Krishna Chitale, and William Lethbridge. The King has also approved of the transfer to the half-pay list of Major William Grant Thorold and Captain Hugh Bixby Luard. The King has also approved of the retirement from the service of Lieutenant-Colonel Percy de Haga Haig and Lieutenant-Colonel Edward Palmer.

VOLUNTEER CORPS.

Artillery: 1st Hampshire (Southern Division Royal Garrison Artillery): Alexander Arthur MacKeith to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Dorsetshire Regiment: Surgeon-Captain A. Emson resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The Woolwich Companies: The undermentioned gentlemen to be Surgeon-Lieutenants: Charles Theodore William Hirsch and Ernest Blair Dowsett.

SOUTH AFRICAN WAR NOTES.

Major Cummins, R.A.M.C., Lieutenant Taylor, R.A.M.C., and Civil Surgeons Edwards, Hinde, Gardner, and Baskin are returning home in the s s. *Montrose.*

Civil Surgeon George Sowden is reported to be suffering seriously from enteric fever (Beaufort, April 21st).

A final meeting of the committee of the Portland Hospital was held on April 27th, when the printed report which had been compiled by a sub-committee was approved. It was resolved that a copy should be presented to each subscriber and that any officer or soldier who had been a patient in the hospital should have the privilege of purchasing a copy at cost price, 3*s.*, on application to the secretary, Major General the Hon. H. F. Eaton, 43, Upper Grosvenor-street, W.

The Imperial Yeomanry Hospital at Deelfontein has now been taken over by the Government.

RECRUITING.

The annual report of the Inspector-General of Recruiting, which has just been issued, shows that the total result of recruiting for the past year amounted to 49,260 men for the regular forces and 37,853 for the militia. The proportion of well-educated men who enlisted in the army during the past five years has risen from 69 to 83 per 1000. It is from this class that the best non-commissioned officers are drawn A considerable number of men are always forthcoming in time of war, as in the case of that in South Africa, for temporary service in an emergency. The highest number of recruits raised for the regular army since the introduction of the short-service system, we learn from the report, was 42,700, obtained in 1899, but that number was more than doubled last year. But the problem that has to be solved is how a sufficient number of recruits are to be obtained in the absence of this war fever, and especially for the maintenance of the increased establishment of the regular army in time of peace. There is no end to the suggestions that have been made for popularising the army and for attracting young men into it without incurring the great outlay which would be entailed by increasing the soldiers' pay so that the army should offer as good a wage as can be had in other sources of labour in civil life outside it. This question of pay is, no doubt, and always has been, one of the radical difficulties in the matter. But it is not everything. In this age of advertising there is not sufficient done to attract men into the army. Our recruiting depôts do not occupy sufficiently public and prominent positions nor are the buildings used for the purpose of the right kind. Buildings intended for recruiting purposes should occupy sites in good open thoroughfares and not be hidden away in back streets and they should be of a superior description to those now provided. Any intending army recruit should have every facility for obtaining all the information he requires at such places. Judging from all that we have heard we should say that the disinclination to enlistment commonly arises from a feeling that the soldier has to forfeit his liberty and that, apart from drills, he has to subject himself to a number of irksome disciplinary details many of which seem to him unnecessary. The young soldier of the present day does not care to be treated like an overgrown schoolboy; he wants greater personal freedom and fewer restrictions than are imposed by our traditional military system. Moreover, the soldier is not satisfied with the system of military stoppages to which he is subjected and we believe that he does not so much desire to have cubicles introduced into barrack rooms as to have these rooms better warmed and lighted in winter and to have more comfortable bath-rooms with warm water laid on.

AHMEDNAGAR.

A good deal of objection has been taken to Ahmednagar as a station for the occupation of Boer prisoners transferred from South Africa to India on the ground of its alleged unhealthiness. Ahmednagar is pretty well known as one of the best and most salubrious stations in the Bombay Presidency. It is situated on the high tableland of the Deccan, and has an excellent climate. To compare Ahmednagar to a sort of Devil's Island to which Dreyfus was banished, as we have somewhere seen done, is absurd. The medical history of the European troops stationed at

Ahmednagar has been satisfactory. We believe that in 1898-99 there were some complaints regarding the water-supply, which has no doubt been since remedied. It is possible, of course, that typhoid fever is not an unknown disease there, but then it would not, unhappily, be easy to name offhand a military station in India or a hill station to which our troops are sent for health that had always been free from enteric fever. And the same thing may be said of South Africa, for we have all had bitter experience during this war of the havoc which this fever has caused among our troops serving there.

IMPROVED MILITARY AMBULANCES.

The present type of military ambulance was condemned by the Royal Commissioners who reported on the care and treatment of the wounded in the South African war, and as a consequence the Master of the Worshipful Company of Coachmakers, who is a colonel in the Honourable Artillery Company, recently offered three prizes for improved designs in ambulances, the principal objects being to reduce the weight and at the same time to increase the ease of carrying and the capacity. The competition has proved most successful and the judges, who have been assisted by an aide-de-camp to Lord Roberts, have awarded the first and second prizes to Messrs. Atkinson and Philipson, carriage manufacturers, Newcastle. One of their draughtsmen, Mr. Terry, gained the first prize, Mr. John Philipson won the second, while the third went to Mr. Butler of the London Polytechnic Carriage Building Class. The drawings can be seen at the Baker-street Carriage Bazaar.

LEAN'S ROYAL NAVY LIST.

The ninety-fourth quarterly issue of this excellent publication, containing information with regard to the war and meritorious services of officers in the Royal Navy, names of famous battleships, dates of all commissions, dates of all retirements, lists of Royal Orders, medals, decorations, honours, &c., Gazette accounts of the Victoria Cross, names of recipients of the Albert Medal, and the societies' medals; dates of birth of flag officers, captains, and officers of Royal Marines; lists of Fellows of the learned societies, private appointments held by retired officers; the causes of special promotion, prizes, and examinations passed, with the relative army rank and time of compulsory retirement, at head of each rank; lists of ships building, &c., has just been issued. The present issue contains a reproduction from an original drawing of Queen Victoria by Paul Raphael Montford. Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, are the publishers.

"SELF-AID IN WAR."

Surgeon-Major T. F. S. Caverhill, of the Lothians and Berwickshire Yeomanry Cavalry, has just issued under this title, at the price of 1*s.*, an enlarged edition of a little book which should prove useful to the private soldier and to the regimental stretcher-bearer. It has special application to cavalry and mounted infantry. The publishers are Messrs. Williams and Norgate of London and Oxford.

ROYAL NAVAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 16th Sir J. N Dick, K.C.B., being in the chair, the sum of £63 was distributed among the several applicants.

THE AFTER-CARE ASSOCIATION.—The report of the council of this association for 1900 states that the past year has been a most encouraging one. The number of poor persons discharged recovered from asylums for the insane dealt with by the association are as follows. During the past 12 months there were 195 cases before the council—not quite so many as in 1899 but the number successfully helped was greater in this than in any previous year. Of these 132 were women and 63 were men. Many have been assisted as in the past by being boarded out in cottages in the country, by grants of money and clothing, by finding them occupation, and in other ways as the council have thought best. Others have had to be declined as it was thought after most careful consideration that they would never again be fit for the struggle of life. The total amount of subscriptions and donations for maintenance in 1900 came to £540 13*s.* 11*d* In 1899 they were £549 8*s.* 1*d.* Communications should be addressed to the Secretary, Church House, Dean's-yard, Westminster.

Correspondence.

"Audi alteram partem."

"REORGANISATION OF THE ARMY MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—I am, of course, quite aware that the highest qualification for planning reforms in the Army Medical Department is to be either a civil surgeon with comparatively small experience in matters military or a combatant officer with no experience in matters medical. Nevertheless, I would suggest that it might be worth while to pretend to think that the members of the Royal Army Medical Corps are themselves qualified to form useful opinions about their own concerns. I am, I need scarcely explain, not so foolish as to really think they are.

This proposal may have increased weight if I prove at once that they emanate from a person without bias in favour of the army medical officer. What is that gentleman? In the first place, he is one who has craved for and got such titles as "Colonel" and "Captain," "with the hope of being mistaken for" that which he is not. "Navalis," a few days ago, pointed out in the *Times* this motive in reference specially to naval engineers, but it is evident he regards as being "in the same boat" all non-combatants who wish to have the titles supposed (erroneously) to belong only to combatants. Now the frequent letters of "Navalis" to the *Times* always appear in the largest print. Their intrinsic merits are inferior to those of most of the letters which that journal presents in small print It is certain, therefore, that he is a man of position who would, of course, judge in a generous and gentlemanly spirit of the motives of other people. Analogous views used to be held, perhaps are still held, by many combatant military officers about military titles for the Royal Army Medical Corps. It is obvious, therefore, that the army doctor is a snob—a person who has assumed certain titles "in order that he may be mistaken for something else."

Secondly, owing to the absence of competition, medical men who enter the army are of inferior knowledge, industry, and capacity. This deduction and this assertion have been made so often that they must be true. In confirmation of the above views I can give my personal experience at the Post graduate College of the West London Hospital. Of late years dozens of medical officers of the Army and Indian Medical Service have attended there. I have found them quite different from the truthful sketch I have just given. If one exception prove a rule, in the remarkable case of the Royal Army Medical Corps in which all the individuals appear to be exceptions, the rule must be proved to absolute demonstration—this said rule being that the army medical officer is a snob and an incompetent, idle fellow.

What I advocate is that we should dissemble, that we should make a pretence of *attaching weight to his own ideas of how to improve himself, and then urge the Government and others to help to develop these ideas.* The true ideas of the army medical officer may be inferred from his conduct. He is constantly seen by us behaving as follows. If he has the opportunity he spends a portion of his time diligently attending a post graduate hospital, working much in the same way as if he were a third-year student. He is not only ready, but eager, to hold a limb, to retract, or to sponge. He is often of high rank, and at first I felt it rather odd to be directing "Colonel" this or "Major" that in student's duties. But his zeal and good manners soon banished that feeling and I now simply have a higher respect for military titles than I ever had before

The army medical officer's view is that he needs courses of practical work in civil hospitals, and especially in those which grant him a recognised position and duties and where there are no unqualified students for him to interfere with. He follows out this view with a modesty which contrasts agreeably with the tone of those who patronise him and of those who libel him It will be remembered that a Member alleged in Parliament that the three principal medical officers in Natal had done no good work because they had been so absorbed in strutting about enjoying their military titles. Sir Redvers Buller himself repelled this slander. One of the three Royal Army Medical Corps colonels thus libelled used, while stationed at Aldershot in 1899, to come to the West London Hospital and work in the manner I have sketched above, and that in spite of the long railway journey. Such men deserve that their own modes of improving themselves should be assisted and developed. This policy could be carried out at the West London Hospital. With encouragement and financial assistance from Government that institution could easily be doubled in size. The two senior assistant physicians and the two assistant surgeons could be promoted to the full staff and no more *civilian* assistant physicians or surgeons be elected. The duties they perform at present should be intrusted to selected men from the Royal Army Medical Corps, each appointed for 12 months, for six as junior and for six as senior. The duties of such a military assistant surgeon would be as follow. During his six months as junior he would assist his surgeon at operations, diligently follow his practice, and on two days a week attend out-patient practice. During his six months as senior he would take charge of out-patients on one day a week and be allowed himself to perform major operations of which he would get a considerable number. But as he would only have this responsible work for six months it should be performed under the superintendence of the permanent surgeon. I do not mean the actual eye of the surgeon. I will give a concrete example. Suppose my military assistant surgeon wished to operate for a strangulated inguinal hernia or to perform an amputation through the knee I should consent; but if he asked me to authorise him to attempt the removal of a calculus from the common bile-duct I should consider what previous experience he had had of such surgery and probably end by taking that case myself and giving him a more suitable one in exchange. But my experience of military post-graduates is that what they generally require in civil hospitals is not snubbing but encouragement. So also there should be a permanent civil out-patient physician and out-patient surgeon who should attend five afternoons a week and be ready for consultation. They should be paid for this work. But their chief inducement would be that each would stand first for the next vacancy for physician or surgeon. The first to fill these offices would be the present juniors.

With regard to expense the management would not need complete endowment from Government, but *backing up*. Hospital beds in London, to a great extent, support themselves. In this way 10 military assistant physicians and 10 military assistant surgeons would pass through a hospital of 320 beds every year—i.e., 200 every 10 years; and there would besides be room for a number of clinical clerks and dressers. It is true that no one can be a good practical physician, still less a good practical surgeon, who has not *recently* been engaged in practising his art. Still, it would be a gain to the Army Medical Department to have available 50 or 60 picked men who had each of them less than two or three years previously spent a year as assistant surgeon in a metropolitan hospital.

I am, Sirs, yours faithfully,

Grosvenor-street, W., April 30th, 1901. C. B. KEETLEY.

To the Editors of THE LANCET.

SIRS,—I have read with interest the article in THE LANCET of April 27th, p. 1224, on the reorganisation of the Army Medical Service. The main point, however, is to get the men. If that is done many of the reforms you suggest will come of themselves. There are three things which attract men to enter a public service—honour, power, and pay. Given the first two and the third may be comparatively very small. At present all three are lacking, so is it wonderful that candidates are lacking also? There seems to me to be a very good reason why the *first two—viz., honour* and *power*—are not accorded with as free a hand as might be to the army medical officer. The combatant officer cannot get out of his head that the army surgeon is simply a civilian in uniform. Can this defect—granted that it is a defect, and I think it is—be remedied? I think it can. Let there be an army medical school to be entered in the same way as Woolwich or Sandhurst is entered, by a competitive examination in arts, and let this school undertake the military and medical training of its students. Let the school be in London, Edinburgh, or where you will, and let the examinations, which, of course, must be such as are recognised by the General Medical Council, be what you will; let the students include the navy and the Indian Medical Service or not, as you please; let it be attached to a large hospital or have its own teaching staff—these, as well as many other points, would require far more space than I can venture to trespass on, but let the students be under military discipline from the very first—that is the point which I wish to emphasise. On becoming legally qualified I would grant them commissions and second a certain number for the purpose of taking up house surgeoncies or while reading for higher examinations. Thus officers would not lose seniority by zeal for their profession.

I have not gone into the question of expense or how much of it should be borne by the student, how much by the State. That, again, is, I think, a matter of detail, but I feel sure that if some such college were started you would get the right sort of candidate to enter it—viz., the student whose ambition it was to be an army medical officer—not, as now often happens, the qualified man who enters the army for want of something better to do.

I am, Sirs, yours faithfully,

April 28th, 1901. R.A.M.C.

"POST-PARTUM HÆMORRHAGE."

To the Editors of THE LANCET.

SIRS,—I, in common, no doubt, with very many other general practitioners, have read Mr. E. Stanmore Bishop's lecture on post-partum hæmorrhage in THE LANCET of April 13th, p. 1069, with great delight, and the result has been that we doubtless shall attempt aortic compression in a like emergency, not as a last resource, but as an adjuvant to other remedies mentioned in text-books. Mr. Bishop quotes Cazeaux, who, I gather from his lecture, thinks somewhat lightly of this means of arresting hæmorrhage. I turned to my Cazeaux ("Traité Théorique et Pratique de l'Art des Accouchements," Paris, 1856), and on pages 932, 933, and 934 I found a totally different statement with regard to the employment of aortic compression. I was so struck with it that I translated the pages mentioned, and I now forward the translation on to you. I will not say that the translation is good, but I think it is fairly correct, and one can see from it that Cazeaux had ideas with regard to aortic compression in 1856 which are not very far removed from those of Mr. Bishop, allowing, of course, for the increase of general scientific knowledge since then. The objections to aortic compression you will see were made by others, and Cazeaux, in my opinion, gives a complete answer to them. You will notice that there is no mention of the faradaic current or of any styptic solution or injection, and they are not even mentioned at all in this edition, as the author, after saying that opium has been suggested by English writers to cause contraction, and after rejecting the idea and having spoken about ergot and been strongly in favour of its use, passes on to transfusion of blood (pp. 934, 935). On one point he differs from Mr. Bishop—all his efforts are for contraction of the uterus, but still he approaches him again when he advises aortic compression lasting for some time, in order that the brain and spinal cord may have enough blood to keep the heart and respiration going. What I should like to know is whether a good old book, such as my 1856 edition certainly is, has been brought up to date and completely spoilt. Hoping you will be able to find space for this somewhat lengthy letter, I am, Sirs, yours faithfully,

ALFRED HUNTSMAN, L.S.A.

St. John's-road, Upper Holloway, N., April 26th, 1901.

TRANSLATION.

M. d'Ornellas has lately sustained a thesis on aortic compression employed in uterine losses. He brings forward many observations as to its application. M. Baudelocque himself has assured me that he has several times succeeded in stopping losses, which from the appearance would seem likely to end quickly in death. This doctor, who contests with Dr. Tréhan the honour of being the first to revive aortic compression, seems to have great faith in the efficacy of this method. A great many facts militate to-day in favour of his opinion. This is how M. Baudelocque, the nephew, advises compression to be made: "Flex the body and legs of the woman on the pelvis, depress, with the four last fingers of one hand, the abdominal wall, immediately above the fundus uteri, you feel the pulsations of the aorta more easily even than one can feel those of the radial. The duration of the compression may last *for some considerable time* without the woman experiencing any inconvenience." M. Baudelocque says he has practised it during a period of more than four hours. This compression is considered by its author himself only as a means of gaining time. He administers almost immediately the "*ergot potion*" whose action soon determines uterine contraction. Aortic compression, advised some time back, had been generally abandoned because the methods of procedure were essentially bad. Some wished to compress it through the abdominal wall and both walls of the uterus; others would introduce the hand into the uterine cavity itself, and would compress the vessel through the posterior wall of that organ. Both these procedures, which are opposed to uterine contraction, ought to be rejected. In spite of the numerous successes which have been attributed to it, several authors, and M. Jacquemier [illegible] and go even so far as to consider it [illegible] follow accouchement the blood whi[illegible] "comes in a great measure from t[illegible] arterial trunk can only favour the reflux of venous blood into the vena cava and its tributaries." Without doubt the utero-placental arteries would not be able to furnish the enormous quantity of blood that a woman just confined sometimes loses in a few moments, and certainly this blood escapes in great measure from the large venous mouths which the detachment of the placenta leaves gaping on the internal surface of the uterus. While agreeing with M. Jacquemier as to this fact, I differ with him as to the conclusion he draws from it. Such are, indeed, the relations of the aorta and vena cava, that it is almost impossible purposely to make compression of the one without compressing the other at the same time. I agree willingly that one is deceived as to the nature of good that one does, and that one should attribute to the flattening of the vein what one boasts of in compressing the aorta; but what does it matter when the practical result—the arrest of the hæmorrhage—is none the less the consequence. M. Jacquemier has done a true service in calling attention to a theoretical error, but I would almost blame him for doing so, if he deprived the practitioner of a last precious resource. I accept, then, M. Jacquemier's theory, but I shall nevertheless continue to compress the aorta, although convinced that at the same time I shall compress the vena cava. Still another objection has been made. Aortic compression, says one, greatly hinders the blood from arriving by the uterine arteries, but it ought necessarily to augment the quantity which arrives by the ovarian, for it is usually performed below the origin of these latter. The objection loses much of its weight since the hæmorrhage is chiefly venous. Out of four arteries which supply the blood two only are patent after aortic compression. It is then a marked advantage. M. Jacquemier considers as useless and irrational the use of ergot while one is using compression. "How can one admit," says he, "that this agent, whose effects are rapid but transitory, can set up stimulation of the uterus when arterial blood has ceased to come there" It is chiefly in acting upon the nerve-centres and in awaking the excito-motor action of the uterine nerves that the drug exercises on the uterus the special action that one recognises in it. To believe that, after having been absorbed in the [illegible]

[illegible] and the contraction of the uterus. In cases, indeed, where the loss has been considerable, all danger is not over when one has succeeded in stopping the hæmorrhage and in determining the contraction of the organ of gestation. Even though not a drop of blood any longer escapes, the amount of this fluid remaining in the body is no longer enough to distribute to all the organs at the same time as to the brain the stimulus requisite to maintain the integrity of their functions, and women sometimes succumb two or three hours after the arrest of the loss, death supervening then because the bulk of the blood is spread equally over the whole area of the circulatory system and because the brain and spinal cord in particular, receiving only a very small portion, lack the stimulus [illegible]

[illegible] inclined plane so that the head occupies the lowest part, one will powerfully assist aortic compression I think then that compression of the aorta and of the vena cava is useful, while the loss is abundant, but that in cases where the patient has lost a large quantity of blood it ought to be kept up for several hours after the arrest of the hæmorrhage and complete retraction of the uterine walls; only in this last case it is requisite to isolate the aorta from the vena cava, so as to exercise compression only on the former of these vessels.

HOUR-GLASS STOMACH.

To the Editors of THE LANCET.

SIRS,—Since reading the proof of my paper on "Hour-glass Stomach"[1] I have found the record of four cases operated upon by Professor Bier of Kiel. The cases are related in an "Inaugural Dissertation" by Eduard Asbeck, entitled "Vier Fälle von Sanduhrmagen und ihre operative Behandlung." The details are as follows:—

Case 1.—A female, aged 51 years. Ten years' history of stomach trouble, loss of weight, pain, and vomiting, but never hæmatemesis; gastroplasty. The ulcer was near the lesser curvature, the cardiac complement much dilated, and the pyloric normal. Recovery followed the operation.

Case 2.—A female, aged 29 years. Stomach troubles since 10 years old. Hæmatemesis two years ago; constant pain since. The stomach was dilated to three finger-breadths below the umbilicus; resistance was felt above and to the right of the umbilicus. Narrowing of the pylorus was found. Gastro-duodenostomy; death. At the post-mortem examination an hour-glass stomach, the pyloric complement of which had been mistaken for the whole stomach, was found. The stricture between the pouches was at the middle of the stomach, and it permitted the passage of one finger only.

Case 3.—A female, aged 39 years. There had been stomach trouble since childhood, with vomiting, pain, and loss of appetite. Above the umbilicus was an area of resistance and tenderness; the greater curvature descended an inch below the navel. A tumour of the size of a hen's egg was found in the middle of the stomach, adherent to the anterior abdominal wall. The tumour was excised and was found to consist of induration round a chronic ulcer. Gastroplasty was performed and recovery followed.

Case 4.—A male aged 56 years. Since 12½ years of age there had been stomach trouble. In the epigastrium there was a tumour of the size of a man's fist. On exploration this was found to be due to adhesion of the stomach and œdema of the anterior abdominal wall. There was an ulcer in the anterior wall between the curvatures which in its contraction had caused an hour-glass stomach. Excision of the ulcer; gastroplasty; death.

I am, Sirs, yours faithfully,

Leeds, April 30th, 1901. B. G. A. MOYNIHAN.

"THE ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—In answer to the letter dealing with the proposed sale of the Royal Orthopædic Hospital in THE LANCET of March 23rd, p. 893, and your leading article of April 6th, p. 1025, Mr. H. H. Marks replied on April 20th (p 1167) accusing a "Hospital Governor" of untruthfulness and of being an enemy of the hospital. He has further made a private communication to you in answer to the arguments against the sale of the hospital. Why should Mr. Marks furnish you privately with information that he denies to the governors of the hospital? Where are the facts and figures in support of his autocratic policy of sale and his detailed criticism of the alternative scheme? For my own part, I can only say that I am prepared to support all statements in my letters except that of the offer of £1200 for the hospital premises on lease, an error which was freely and frankly withdrawn by the senior *surgeon to the hospital.* The latter gentleman has endorsed my statements, so that Mr. Marks can hardly avoid an answer on the score of anonymous criticism. My card is inclosed and my name is well known to THE LANCET. My name will be forthcoming whenever necessary. It is open to Mr. Marks meanwhile to answer the criticisms of the senior surgeon—if he can. I am, Sirs, yours faithfully,

London, April 29th, 1901. HOSPITAL GOVERNOR.

"THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES."

To the Editors of THE LANCET.

SIRS,—The National Friendly Society proposes to start a branch in the town where I live, the population of which is about 4000. My fellow practitioners and self have been asked to undertake the work. We have agreed to act in unison regarding the matter and are now considering whether to accept or refuse their terms Our objections are: the society has no wage limit; a member need not join up to the full extent of his income; the society's fees are smaller than our usual ones; and the working and agricultural labourers are already well provided for with clubs. We should be glad to have your advice on the subject. I am, Sirs, yours faithfully,

April 29th, 1901. W. E. T.

⁂ Mr. E. W. Brabrook in a letter published in our columns last week says that the friendly societies "desire to pay a fair price for the services rendered to them. They are neither beggars nor sweaters. How is the fair price to be ascertained? The medical man is to say, taking the society as a whole, for what sum paid by every member, whether sick or well, he is willing to attend those who are sick." Mr. Brabrook writes as one having authority to control the policy of the friendly societies and we recommend our correspondent and his colleagues to ascertain how far the National Friendly Society will see the situation with Mr. Brabrook's eyes. It is a great thing that all the medical practitioners of the town have agreed to have a common policy. We recommend that they fix a proper price for which they are willing to attend the proposed new branch and await the result.—ED. L.

---

[1] THE LANCET, April 27th, 1901, p. 1190.

To the Editors of THE LANCET.

SIRS,—Mr. Brabrook's letter in THE LANCET of April 22nd, p. 1232, is most valuable and instructive. He not merely implies, but actually states outright, that a medical man's action in "taking a club" is governed by ordinary commercial rules, and is not in any way "charitable." He says of the societies: "They desire to pay a fair price for the services rendered to them. They are neither beggars nor sweaters." This is a *petitio principii* with a vengeance. It is unfortunately also the exact reverse of the facts. When even Mr. Brabrook can fall into such an astounding error, which absolutely destroys the value of an otherwise good letter, what hope is there of conciliation? None, whatever, Sirs, in my opinion. The fight is as inevitable as was the Boer war. The only question for the profession is: Will its members organise and win, or prefer disunion and be beaten in detail?—I am, Sirs, yours faithfully,

EXPERIENCE.

April 29th, 1901.

"BICYCLING IN LONDON."

To the Editors of THE LANCET.

SIRS,—Your correspondent "M.D. Lond.," whose letter appeared in THE LANCET of April 27th, p. 1236, is illogical. When she drives in a hansom cab she encounters "horses that flounder and threaten to fall," but no sooner is she mounted on her wheel then behold "every horse is well under control." It is perfectly true, as stated in your annotation in THE LANCET of April 20th, p. 1154, that bicycling in London, when indulged in by women, is fraught with danger, although their machines are safer than men's, because so much easier to dismount from, while their upright seat allows them to survey their surroundings with facility. The agent responsible for the downfall of so many bicycling women is the too long petticoat or skirt. Until women can bring themselves to subordinate their clothing to utilitarian ends they will do well to refrain from bicycling in London. I am, Sirs, yours faithfully,

A CYCLIST SINCE 1871.

April 27th, 1901.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The St. John Ambulance Association in India.—Still Further Increase of the Plague Epidemic.—Change of Stations for British Troops.

FOR many years the ambulance association in connexion with the Order of St. John has recognised the extensive field for its work which India presents, but the attempts at instruction in first-aid have been spasmodic and individual. It is proposed now to institute various centres in India, and Major Yate of the central executive has been appointed organising secretary and is at present touring for the purpose Influential committees have been appointed at Calcutta, Madras, and Bombay, and local enthusiasts have been secured to carry out the work. Some organisation of this kind was absolutely necessary, and amongst the European population the instruction ought to be very popular. Every British sojourner in India is liable to accident of some kind or another, and he is often so placed that professional skill is beyond his reach. It is therefore particularly necessary that his comrades should be able to render first-aid. I need only mention planters, sportsmen, volunteers, railway officials, and police to show the immense field for the work of this association. I do not anticipate much success with the natives of India, either with the educated classes or by a modified elementary course of instruction with minor officials. The object of the association and its teaching must be first assimilated by the British residents. The movement has been already taken up, and I understand that many classes have been started. Probably, in no other country could the benefit of a knowledge of rendering first-aid prove so useful as to the British residents in India, and the movement should meet with every success.

The record of plague for the past week shows a still further development. The total deaths number 11,606 compared with 11,480 during the previous week, and 4546 in the corresponding week of last year. There has been a further increase in the districts of Bengal—the country surrounding the cities of Patna and Gya contributing most to the 7881 deaths returned for Bengal. In the cities it has declined and there is a marked abatement in Calcutta. The disease continues to spread in the Punjab. Elsewhere there is little change. The official notification of areas affected includes the Bombay Presidency, the Karachi district (Sind), the Salem district of the Madras Presidency, the towns of Calcutta and Howrah and the Twenty-four Parganas, Patna, Gya, Shahabad, Saran, Musaffarpur, Darbhanga, Monghyr, the Santhal Parganas, Hazareebagh, Palaman and Maubhum districts of Bengal, the Benares and Ballia districts of the North-west Provinces, Bangalore (the city and the civil and military stations), Mysore city, and the Kolar goldfields. In addition there are districts affected in Baroda territory and in Rajputana and in several districts in the Punjab. The plague has at last attacked Agra, presumably through an imported case, and thus the disease shows further signs of attacking slowly town after town up the course of the Ganges. Hitherto all this densely populated area has escaped. With the likelihood of recurrences year after year as in the cities first attacked there is little chance of the epidemic disappearing for a long time to come.

I am glad to say that the military authorities of the Government have at last recognised the dangers of Dum-Dum to the health of British troops. The garrison is to be reduced considerably all the year round. A larger number of men will in future be kept during the summer at Lebong (Darjeeling) and the force at Dinapur will be increased during the winter.

April 13th.

GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE Thirtieth Congress of the German Surgical Association was opened in Berlin on April 10th, Professor VON CZERNY (Heidelberg) being in the chair.

Renal Surgery in the Nineteenth Century.

Professor KUSTER (Marburg) read the first paper. In it he gave a review of what had been done in renal surgery since the time of Sir T. Spencer Wells and Dr. Gustav Simon, who were the first to perform such operations. The mortality, which was at first 44·6 per cent., has now fallen to 16 per cent, this result having been obtained not only by an improved method of operating, but especially by the greater accuracy of diagnosis. Cystoscopy and catheterisation of the ureters now enabled surgeons to ascertain whether one kidney or both kidneys were affected. In cases of moveable kidney nephropexy gave the best results, being followed by only 6 per cent. of relapses. For wounds of the kidney suture and packing (tamponade) were to be preferred to total extirpation, as suggested by Dr. Simon. In suppuration of the kidney the course to be followed differed according to the cause of the suppuration. In tuberculous disease nephrectomy with extirpation of the ureter was the best operation; when there were renal calculi, and also in cysto-nephrosis, nephrectomy was preferable. For malignant growths total or partial nephrectomy was necessary. The lumbar incision was of course the only advisable one, but for large growths laparotomy must be sometimes performed.

The Progress of Diagnosis in Renal Surgery.

Dr. CASPER (Berlin) gave an account of his methods of ascertaining whether a kidney was healthy or not. By catheterisation of both ureters the urine of each kidney was collected separately and was then examined as to its freezing-point, the amount of nitrogen contained in it, and the amount of sugar which followed the administration of phloridzin. It has been found that the freezing-point of urine varied according to the condition of the kidney from which it came, for the healthier the kidney was the more nearly did the freezing-point of the urine approach that of water. A healthy kidney excreted a greater amount of nitrogen than an unsound one and the amount of sugar obtained by the administration of phloridzin was also smaller in disorders of the renal function. Dr. Casper mentioned 14 cases in which by his methods the existence of renal troubles was ascertained previously to operation, although other methods had given no trustworthy results.

Treatment of Enlarged Prostate.

Dr. GOLDMANN (Freiburg) proposed that in cases of enlarged prostate recourse should be had to cystopexy—i.e., suturing of the anterior wall of the bladder to the abdominal wall. In one case he found at the necropsy that the internal orifice of the urethra had become wider by the traction of the cicatrix.

Operations for Goitre.

Professor KOCHER (Berne) presented a report on the second series of 1000 operations performed by him for goitre He said that he now employed excision almost exclusively, enucleation being resorted to in rare cases only. In ordinary goitre the mortality was only 4 per cent. Septicæmia never happened. One patient died from cachexia strumipriva and one under the anæsthetic. He now used neither chloroform nor ether but only local anæsthesia according to Schleich's method. In the last 302 cases no death occurred. He then drew attention to struma profunda, in which condition diagnosis was often difficult The patients complained of dyspnœa or palpitation, so that the disease was sometimes believed to be cardiac trouble or bronchitis, especially when it was accompanied by cough If moveable the tumour might appear above the sternum during a fit of coughing. If it were not moveable the diagnosis might be made by means of the x rays; paresis of the recurrent nerve also sometimes appeared. The operation for struma profunda was very difficult. All the arteries must first be ligatured; when there were adhesions between the tumour and the surrounding tissues "morcellement" was necessary. In his 1000 cases there were 22 of struma profunda. As to the internal treatment of goitre, he said that preparations of the thyroid gland of animals had not given such good results as were at first expected and, moreover, undesirable symptoms often appeared during their administration. Iodine was preferable. Phosphate of soda might also be administered, because it counteracted the hypersecretion of the gland and therefore caused considerable decrease of its size.

Professor KRASKE (Freiburg) said that he had performed 420 operations for goitre, of which one-third were in men and two-thirds in women. In 220 cases extirpation was performed. Ten of the growths were malignant, one was metastatic, and two were accessory. In four cases of enucleation there was severe hæmorrhage afterwards. He used no general anæsthetic, but Schleich's method exclusively. The number of cases of goitre increased considerably from year to year, notwithstanding the use of thyroid preparations—a class of remedies which never produced a permanent cure but only a temporary amelioration.

Professor KÖNIG (Berlin) asked how much of the gland must be left intact to avoid cachexia strumipriva.

Professor KOCHER replied that at least one-fourth must be left.

Disinfection of Infected Wounds.

Professor VON BRUNS (Tübingen) said that the disinfection of wounds by chemical agents was practically impossible; the substances used for this purpose would have to be applied in so concentrated a form that poisoning would be the consequence Disinfection by physical means, such as drainage, large incisions, &c., gave better results, but was not always available. Professor von Bruns had found that pure carbolic acid was less toxic than concentrated solutions He only put from two to six grammes (from 30 to 90 grains) of pure carbolic acid into a wound. The effect was a strong antiseptic action, and the discharge from the wound afterwards became so small that in a case of adenitis the dressing was able to be left undisturbed for three weeks. He had also found that brushing the wound with alcohol was the best way to avoid carbolic acid poisoning.

Professor KÜSTER said that pure carbolic acid was a caustic and that the actual cautery would act in the same way.

Professor KÖNIG recommended incision followed by draining and attributed the good results obtained by Professor von Bruns, not to the carbolic acid, but to the other parts of the treatment. He had used chloride of zinc for many years.

The Indications for General Narcosis and Local Anæsthesia

Professor VON MIKULICZ (Breslau) said that chloroform and ether were both of them dangerous to some extent. The surgeon must not use either ether or chloroform exclusively but must select one or other according to the nature of the case and the condition of the patient. Ether was by no means so free from danger as had been supposed. Local anæsthesia was becoming more and more used even in major operations, especially since Koller's discovery of cocaine and Schleich's anæsthesia by infiltration. Schleich's method had been used by Professor von Mikulicz in a great many cases. It had, however, the drawback that the infiltration caused the tissues to become so swollen that the operation was sometimes made very difficult by the impossibility of distinguishing the different layers of the part—as, for instance, in operations on the mamma In laparotomy Schleich's method was very good for the incision of the abdominal walls, but in the subsequent stages it was often insufficient, and in those cases general anæsthesia had to be induced. For operations on the extremities and for minor operations in general this method was undoubtedly preferable to general anæsthesia. General practitioners now used Schleich's infiltration anæsthesia in the majority of cases. A collective investigation conducted by Professor von Mikulicz amongst the practitioners of Silesia showed that general anæsthesia had been used in 38,000 cases and Schleich's anæsthesia in 103,000 cases. In the choice of a general anæsthetic the surgeon must be guided by the condition of the patient. Chloroform was liable to interfere with the action of the heart, and ether should therefore be employed for patients suffering from cardiac trouble; when bronchitis or other diseases of the lungs existed chloroform was preferable to ether. When pneumonia followed an operation it must not always be attributed to the anæsthetic, for in some conditions, such as strangulated hernia, there was a marked tendency to pneumonia independently of the anæsthetic It had even been stated that pneumonia occurred in these cases when no anæsthetic had been administered Pneumonia often occurred because the patient had caught cold during the operation, and it was recognised that pneumonia after operation had considerably decreased since operating-tables were provided with heating apparatus. Professor von Mikulicz generally preferred ether, an excessive dose of which was not so easily given as in the case of chloroform.

Professor BIER (Greifswald) then gave an account of his injections of cocaine into the lumbar arachnoid, which were noticed in THE LANCET of March 16th, 1901, p. 825. Although himself the author of this method he was more sceptical than other surgeons as to its advisability. There was no doubt that a total analgesia of the lower extremity could be obtained, but undesirable symptoms were very frequent. Headache, vomiting, giddiness, shivering, &c., were met with after the injections The cause of these complications was that the cocaine made its way through the spinal arachnoid into the brain. He had made experiments in the hope of finding means of preventing the cocaine reaching the brain, but was not yet able to give details. When weak solutions were used the anæsthesia was less complete, but complications nevertheless followed. Tropacocaine was reported to be less dangerous than cocaine, but Professor Bier was of opinion that his method was not as yet adapted for use in general practice.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Arsenic in Beer.

DR. NATHAN RAW, the medical superintendent of the [illegible] some interesting evidence before the [illegible] -d Kelvin which is [illegible] sence of arsenic in beer. Dr Raw stated that the recent epidemic of arsenical poisoning in Liverpool did not appear to be as extensive as that in Manchester, although some of the cases had been of a severe type During the last three years there had been 226 cases of peripheral neuritis in the Mill-road Infirmary, of which number 153 had presented symptoms which might be attributed to the presence of arsenic. Of these 226 patients 51 had died, the apparent cause of death being general asthenia with cardiac failure in most cases. During the years 1898 and 1899 the number of cases of neuritis averaged 30 a year, but a sudden increase was first noted in June, 1900, which steadily progressed until the end of 1900 Reviewing the epidemic as a whole he had noted the cases to be divided into two classes—

acute and chronic. Of the former he had only seen 17 cases. They occurred late in the epidemic, about the beginning of December. The patients had the appearance of having been suddenly and acutely poisoned with a large dose of arsenic. The symptoms, although acute for a few days, passed off, and in all cases the patients were discharged as recovered. The chronic cases comprised by far the greater number, and on admission they presented the usual symptoms of peripheral neuritis and had the appearance of some slow and chronic form of poisoning, attributed at that time to alcohol. Dr. Reynolds's paper was the means of his attention being drawn to the presence of arsenic, which of course explained the cause of the epidemic. He had noticed that since the epidemic of arsenical poisoning in Liverpool the amount of alcoholism had decreased.

Mr. Benn Wolfe Levy and the Freedom of the City.

The City Council are about to confer the freedom of the city upon Mr. Benn Wolfe Levy in recognition of the benevolent spirit which animated him in the matter of the David Lewis trust. It will be remembered that the late Mr. David Lewis left his large fortune to his two nephews, of whom Mr. Levy was one. He also left a sealed letter expressing the hope that his legatees might devote the money for the benefit of the people of Liverpool and Manchester. Mr. Levy and his co-trustee at once gave effect to this direction, although they were not legally bound to do so. The outcome of this generosity, as far as Liverpool is concerned, was the erection of the New Northern Hospital (now known as the David Lewis Northern Hospital). Funds were also provided from the same trust for the building of new homes for nurses in connexion with the Victoria Jubilee Memorial. The trustees of the fund also acquired a site for the purpose of a recreation ground for the people in the east end of the city, and they are also erecting a handsome pile of buildings on the site of the old St. James's Market for the purpose of homes for single men, besides a library and other institutions for the people of the south end of Liverpool. A large sum of money has been devoted to these undertakings, and Mr. Levy, as the head of the trust, has travelled long distances to inspect the best-equipped hospitals, in order that Liverpool may possess in its new Northern Hospital one of the finest buildings of its kind. Mr. Levy has also devoted a good deal of time in superintending the erection of the new hospital, and it is generally acknowledged that the David Lewis Northern Hospital is a building thoroughly up to date in every particular.

The late Arthur Samuels, M.D. St. And., &c.

Dr. Arthur Samuels succumbed to an attack of pneumonia of short duration on April 21st, at the age of 70 years. He received his medical education in Dublin and obtained the Membership of the Royal College of Surgeons of England in 1858. He graduated as M.D. of St. Andrews University in 1862. He was an honorary physician of the Liverpool Hospital for Consumption for a number of years, and he also served the ratepayers of Everton for over 20 years as a member of the burial board. Dr. Samuels was a man of exceedingly amiable disposition and it can be truthfully said of him that he had troops of friends and was never known to have made an enemy.

A University for Liverpool.

At a special meeting of the Council of University College, under the presidency of the Earl of Derby, K.G., held on April 17th, the question of converting University College into Liverpool University was discussed, and the following motions were unanimously adopted :—

1. That, while gratefully acknowledging the advantages which have accrued to University College, Liverpool, by its association with *Victoria University*, this Council is of opinion that a university should be established in the city of Liverpool; that this Council will welcome a scheme with this object upon an adequate basis, and that a committee be appointed to consider and report upon the whole question, with power to make inquiries and to communicate with other bodies.
2. That the committee consist of all the members of Council, with power to associate with them any other persons whom they may think fit.

April 30th.

SUBSTANTIAL HELP TO THE METROPOLITAN HOSPITAL.—The chairman of the Metropolitan Hospital, Kingsland-road, announced at the annual meeting of the governors and subscribers, held on April 29th, that the trustees of the late Mr. Zunz had awarded to the institution £1000 annually for 10 years.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Plague Precautions in Ports.

THE West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health has among its members so many port medical officers that it is not at all surprising to find the question of the introduction of plague brought forward at the meeting on April 18th at Plymouth, although it had been discussed at Bristol as recently as February last. The medical officer of health of Plymouth (Mr. F. M. Williams) urged the need for new regulations by the Local Government Board in lieu of the Order of 1896, in view of the opinion, now pretty generally held, that rats are the prime factors in the spread of the disease. It appears that the dock authorities in Plymouth do not insist upon the gangways of vessels being raised at night, nor are the cable ropes protected with iron collars as at Bristol, Liverpool, and elsewhere, in order to prevent rats from coming ashore. Mr. Williams considered, also, that regulations should be framed with regard to the examination of baggage, though he did not state precisely how this should be carried out, and other speakers, notably Mr. J. O. Heaven of Bristol, were of opinion that the proceeding would not be at all practicable. Having regard to the return of the troops from South Africa and to the possibility of plague being brought into this country from the Cape, it is very satisfactory to learn that the military authorities have given the port sanitary authority of Plymouth a free hand in dealing with infected soldiers and have placed at the disposal of the authority Drake's Island, one of the forts, and if necessary Staddon Heights, and have agreed to pay all costs that may be incurred by the authority.

A Low Death-rate.

The death-rate of Porthcawl in 1900 was only 6·2 per 1000. This Welsh seaside resort has a resident population of about 2000.

Housing of the Working Classes in Swansea.

The Swansea Corporation are about to erect cottages for working men. They are to cost £194 each and will be let at a rental of 6*s.* weekly. Each house will contain a parlour, kitchen, and scullery, three bedrooms and a bathroom. This last is a distinct innovation in Swansea cottages and it will be interesting to see whether it will be appreciated, for it is remarkable how little value, as a rule, is attached to a bathroom by the working classes. Even in the coal-mining districts, where the colliers have their daily baths on returning from work, they seem to prefer the wooden tub made out of half of a 40-gallon cask before the kitchen fire rather than to retire to a separate bathroom. In one Glamorganshire village where the houses are nearly all owned by the proprietors of the colliery bath rooms were erected leading out of the kitchens, but the long iron baths are never put to their legitimate use and as often as not are found filled with coal or used as a general receptacle for odds and ends.

Royal Albert Hospital, Devonport.

A successful bazaar and café chantant in aid of the funds of this hospital was opened by Lady Charles Scott on April 23rd. The annual income of the Royal Albert Hospital averages £4000 and the expenditure amounted to £4500. Recently improvements have been made in the building at a cost of £2000. Towards this sum Sir John Jackson promised £500 provided £1500 were raised by a certain date, and at present only £182 are needed to obtain the promised sum. The whole of the proceeds of this bazaar will be devoted towards the expenditure of the hospital and not towards the building fund for the recent improvements.

Crownhill Convalescent Home.

The annual meeting of the subscribers of the Crownhill Convalescent Home near Plymouth was held on April 19th under the presidency of Sir Massey Lopes. The medical report stated that 246 patients had been admitted during the year 1900. The financial statement showed that the income amounted to £478 and that a favourable balance of £7 remained. Sir Massey Lopes in appealing for increased subscriptions alluded to the munificence of the founder of the home, Dr. C. A. Hingston

April 29th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

THE graduation ceremony closing the winter session of the university took place on April 23rd. Among those who received the honorary degree of *LL.D.* were *Andrew Cecil* Bradley, M.A., formerly professor of English literature in the University; Charles Scott Dickson, K C., M.P., Solicitor-General for Scotland; and Arthur William Rücker, D Sc., F.R S., secretary of the Royal Society. The degree of M.D. was conferred on Alfred George Newell, M.B., C.M., Ursula Chaplin, M.B., C.M., and George Mervyn Sydenham, M.B., C.M. Mr. Newell was "commended" for his thesis on "Insanitary Areas and Houses in Bombay and their Relation to Plague, with a Suggested Scheme of Improvement." The following medical graduates received the degree of D Sc.: Walter King Hunter, M.D., B.Sc., Adam Brown Kelly, M.B., B.Sc., Robert Stevenson Thomson, M.D., B Sc, and James Sim Wallace, M.D., B Sc. Among the University prizes the Dobbie-Smith gold medal for the best essay on a subject within the limits of the science of botany with an illustrative series of microscopic and macroscopic specimens was awarded to Daisy Annabella Murdoch Clark, M.B, B Sc., the junior Arnott prize in physiology was divided between William B. Morton Martin and John Logan Stewart, M.A., and the senior Arnott prize was gained by Joseph White, M.A., B Sc. The most distinguished M.A. for the year (1900) was adjudged to be Mabel Atkinson; this lady accordingly received the Thomas Logan Memorial medal. The various class prizes and medals were also announced, Miss Gertrude Bostock, B.Sc., winning at Queen Margaret College medals in medicine, in surgery, and in pathology. The ceremony was closed by an address from the very Rev. Principal Story, LL.D. The Principal first made acknowledgment of the benefactions received by the University during the academic year. These included the sum of £11,000 presented by the late Mr. T. B. Thomson for the *reconstruction of the anatomical school, a sum of £1200 for* the foundation of a scholarship in pathology in memory of the late Professor Joseph Coats, and various other donations towards objects connected with the arts and science faculties. The Principal also intimated that the appeal for funds to increase and improve the medical and scientific laboratories will shortly be placed formally before the public, and he announced that the subscription list towards this object already reached £34,000, this sum including two donations of £5000 each. In connexion with the celebration of the ninth jubilee, which is to take place on June 12th, 13th, and 14th, he stated that representatives were expected from the English, Irish, Colonial, European, and American universities. The remainder of the address was occupied with a discussion of the true nature of education and of the relationship of the University to commercial and technical education. One feature of the jubilee celebrations is to be the issue of a memorial album to which many distinguished graduates have undertaken to contribute. Reminiscences of the old days when the college was situated in the High-street are to be supplied by Lord Lister, Sir Henry Campbell-Bannerman, Professor James Bryce, Sir Henry Craik, Sir William T. Gairdner, and Principal Rainy. The Rev. Henry Grey Graham has promised to write a historical sketch of the University and an article on the development of the medical faculty will be contributed by Sir Hector Clare Cameron. Other contributors include the Master of Balliol, Sir Lewis Morris, Mr. W. E. Henley, and Mr. Neil Munro. The album is to contain illustrations by Mr. J. Guthrie, R.S.A., Mr. D. Y. Cameron, and Mr. Muirhead Bone, and the representatives of "Young Glasgow," both in art and literature, will add to the interest of its pages. The corresponding secretary is Mr. Archibald Leitch, University Union, Glasgow. At the April meeting of the University Court Dr. J. Hutchison was appointed a representative on the board of the Victoria Infirmary in place of the late Dr. James Dunlop. It was agreed to grant the use of the chemical department for the annual meeting of the Society of Chemical Industry. A resolution received from the Students' Representative Council recommending that the degree of Ch.M. be altered to Ch.D., thus granting a doctorate in surgery, was remitted to the Senate for consideration.

Handsome Bequests to Hospitals.

The trustees of the late Mr William Houldsworth have under the terms of his will intimated the following bequests: Glasgow Royal Infirmary, £3500; Glasgow Western Infirmary, £3500; Ayr County Hospital, £1000; Royal Hospital for Sick Children, the Association for the Relief of Incurables, and the Sick Poor and Private Nursing Association, Glasgow, each £250. A number of smaller sums are also granted to several special hospitals and associations. Under the same will the University of Glasgow receives £2000 and the West of Scotland Technical College £1500.

Small-pox in Glasgow.

The decline of the epidemic continues. The new cases registered during the past fortnight numbered 67, as against 92 in the previous fortnight, and the total actually under treatment has fallen to 130. No new cases during the fortnight occurred in either the north-western or south suburban districts of the city. According to recent statements of the convener of the Health Committee 302,000 of the citizens have been revaccinated since the beginning of the year.

Pharmacy Prosecutions in Glasgow.

The Pharmaceutical Society continues to give attention to the sale of poisons in open surgeries. During the past week two cases have occurred in which assistants in such surgeries, unqualified under the Pharmacy Act, have been convicted of the sale of scheduled poisons. *In one of the cases the poison*—red precipitate in the form of an ointment—was not even labeled as required by law, and the sheriff, regarding this as an aggravation of the offence, inflicted a fine of £4 and costs. In the second case two scheduled poisons—viz., carbolic acid and tincture of opium—were sold, and the accused was fined £6 and expenses. The legal representative for the defendant stated that his client had been prevented from passing the final examination by extra work due to the outbreak of small-pox. There seems to be no limit to the apologetic burden to be placed to the debit of this unfortunate epidemic.

April 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Victoria Hospital, Belfast.

MR. WILLIAM CRAWFORD, who has recently been appointed chairman of the Board of Management of the Royal Victoria Hospital, Belfast, has decided to present the hospital with a new and up-to date ambulance which will be of the greatest benefit to the patients.

Royal University Graduates' Association.

At a very largely-attended meeting of the council of the Royal University Graduates' Association held in Belfast on April 26th, Dr. W. A. McKeown (President of the association) being in the chair, the following resolutions were unanimously adopted:—

[illegible] welcome the assurance given by His Excellency [illegible]

Irish university education [illegible] main purpose of which was to establish a university in Dublin for Roman Catholics and the conversion of Queen's College, Belfast, into a provincial university for the "great Presbyterian bodies of the north"

3. That whilst we heartily approve of the scheme for the more [illegible] of Queen's College, Belfast, we are of opinion that [illegible] itution by admitting to a share [illegible] the graduates and of private donors as well as [illegible] ive public bodies, county and municipal. [illegible] the Royal Commission into Irish [illegible]

The Admission of Patients to Asylums.

An interesting point bearing on the method of admission of patients into asylums came up at an inquest in Belfast, on April 26th. Briefly, the facts were as follows. A woman, the wife of a labourer, showed signs of nervous disease and a medical man told her husband to get a line for her admission to the asylum. He procured a "blue" form and took it to another medical man who had also attended his wife, but he refused to certify her as insane. He then consulted the first medical man who advised him to go to the relieving officer for a line for the union infirmary. The woman was taken to that place, but at her own request the husband took her home, and on April 20th she became so bad that he brought a third medical man, who recommended him to get a magistrate's order for her admission to the asylum, but he found the court was over when he got there. On April 22nd the husband made an information and procured a warrant, and that evening a police-sergeant removed her to the police-office in the covered police-van. In the police office she became weak, a medical man had to be sent for to see her, and on recovering she went with her husband and the police-sergeant to the workhouse, where she died two days afterwards from exhaustion following upon mania. The coroner said that it was a barbarous system which was in practice at present of taking insane women down to the police-office and bringing them to the petty sessions court to be examined there. A simple and effective plan would be to have the "blue" form filled up by the dispensary medical officer and two magistrates brought to the house without any fuss or any trouble or any worrying of the insane person, and then the patient could be removed to the asylum where expert treatment could be put in force at once. He hoped in future that the plan he had mentioned would be adopted. The jury returned a verdict in accordance with the medical evidence and added a rider to the effect that they considered the procedure for the admission of lunatics to the district asylum as shown in the case was cumbersome and barbarous and that the simple plan of getting the dispensary medical officer of the district in which the lunatic resided to certify insanity in the presence of two local justices at the house of the lunatic, and that the lunatic should be sent direct from there to the district lunatic asylum, was the more humane plan.

Queen's College, Belfast.

Dr. P. Redfern has contributed £500 to the new endowment fund of Queen's College, Belfast.

The late Dr. C. K. D. Tanner and the Medical Profession in Cork.

Dr. Tanner had been intimately associated with the members of the medical profession in Cork for many years. He had studied arts and medicine in the Cork Queen's College and graduated in both at the late Queen's University. His father had been professor of surgery at the Cork College for a number of years and enjoyed a large and remunerative practice in the South of Ireland. Dr. Charles Tanner succeeded his father as surgeon to the Cork South Infirmary and a brilliant professional career seemed to be in store for him. However, he preferred the excitement of parliamentary life and finally ceased to practise his profession. Though, as is well known, he was a very pronounced politician, yet he managed to preserve the friendship of many whose political opinions were entirely at variance with his. Many of his professional associates in Cork knew that his health had been gradually breaking down for a number of years and they saw with regret that the end could not be long deferred. It is well known in Cork that in private life Dr. Tanner was a most courteous, genial, kind-hearted friend, and a vote of condolence passed to his relatives at the last meeting of the Cork Medical and Surgical Society fittingly expressed the kindly feelings which at all times subsisted between him and the other members of the profession in Cork.

April 30th.

PARIS.

(From our own Correspondent.)

Death of Dr. Napias.

Dr. Napias, director of the Assistance Publique, died on April 29th, at the age of 59 years, owing to disease of the liver from which he had for some time past been a sufferer. Born in 1842, at Sezanne (Marne) he entered the medical department of the navy in 1863, and retiring in 1877 he returned to Paris where he took his doctor's degree after which he gave his whole attention to hygiene. In 1877 he founded, together with Budin, Gubier, Dubois, Laborde, and Pinard, the Society of Public Medicine and Professional Hygiene, of which society he was the secretary-general. He was appointed departmental inspector of factory children and became president of the Council of Inspectors-General of Charitable Institutions, a member of the Consultative Committee of Public Hygiene of France, a member of the Superior Council of the Assistance Publique, and finally on May 12th, 1898, director of the Assistance Publique. Dr. Napias was a man of the very greatest merit and was loved and esteemed by all who knew him. He was absolutely devoted to the work which he carried on for the last three years and which he was most anxious to protect from the attacks made upon it, attacks which were often unjustifiable, by granting universally demanded reforms. As a scientific writer he stood high and among his works I may mention: A Manual of Industrial Hygiene—a Study of the Progress of Hygiene in France from 1878 to 1882 (with A. J. Martin); Isolation Hospitals of Europe; Poor-law Relief in the Department of Sambre et-Loire; and Hospital Hygiene and Poor-law Relief (with A. J. Martin). He had been a member of the Academy of Medicine since 1897 and was also *officier* of the Legion of Honour.

An Improved Method of Applying the Treatment of Finsen.

The treatment of lupus by photo-therapeusis, after the method of Finsen, has been adopted in Paris as in other scientific centres of Europe. There is one set of apparatus in working order at the St. Louis Hospital, the great French school of dermatology, and another is at work in a private dermatological institute. There are, however, two grave obstacles in the way of applying this treatment in a widespread manner, one being the length of time necessary and the other the expense. Each sitting lasts one hour and requires the attendance of a specially trained nurse for each patient. A great step in advance has, however, been taken by means of the apparatus devised by M. Lorted and M. Genoud of Lyons. M. Gaston has just given a set to the French Society of Dermatology and Syphilography. The apparatus is based on the same lines as that of Finsen but is much more powerful, and the condensers necessary in Finsen's apparatus have been done away with by intercepting the luminous rays as near their point of origin as possible As in Finsen's apparatus there is a special arrangement for cooling the rays The results are superior to any hitherto attained. It is possible to affect an area almost double that formerly operated upon and the photo-chemical intensity of the rays is so great that the time of exposure necessary is reduced from one hour to 15 minutes. Besides the economy in attendants which this brings about it must be noted that Finsen's apparatus required a current of from 60 to 80 ampères, which is not to be met with everywhere, while the new apparatus only requires a current of 10 or 12 ampères, which the ordinary electric-light mains can easily supply. These important improvements will allow the light treatment to be much more generally used than heretofore. Its results are without doubt remarkable, but up to now the expense attendant on the treatment has precluded its general application.

The Employment of White Lead.

A vigorous campaign is being carried on against the use of *blanc de céruse* (carbonate of lead) in painting. This is in accordance with a resolution passed by the Superior Council of Hygiene of France which ranked white lead among the deadly poisons. It is well known that this pigment is the common cause of the lead-poisoning so widespread among painters. The Director of Posts and Telegraphs has forbidden its use in all the offices under his control, and in addition the painters of Grenoble have gone on strike to demand that all employers should use zinc white instead of lead white. Zinc white is far less poisonous but more expensive, as owing to its want of "body" more coats have to be laid on. The painters have sent out a circular to all medical men in France asking for their support. They also ask for the subscriptions of medical men to be paid into the strike fund in the name of those principles of hygiene and sanitation upon which medical men are always insisting.

May 1st.

Queen Victoria Jubilee Convalescent Home, Clifton.—At a town's meeting held at Bristol on April 26th under the presidency of the Lord Mayor it was resolved to appeal for donations to the Queen Victoria National Memorial and to a local fund towards completing the endowment of the Queen Victoria Jubilee Convalescent Home, Clifton.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Sydney Hospital.

THE annual meeting of the governors of this hospital was held on Feb. 26th, His Excellency the Lieutenant-Governor presiding. The annual report for the year 1900 showed that 3701 patients had been admitted Of these 404 died, 2084 were discharged, and 984 were relieved. The average number of beds occupied was 296, the largest number being 314 and the smallest 280; the average duration of stay in days was 27. The number of accidents and urgent cases admitted without recommendations was 1664; the number of cases admitted on Government orders was 1349; and the number of admissions on subscribers' orders was 115. The number of patients who contributed to their maintenance was 573. During the year 2269 operations were performed. The new cases treated in the out-patient department during the year numbered no fewer than 25,829, and the attendances numbered 91,002. The President stated that during the past year the operations of the institution had been eminently satisfactory and the board had been able to carry forward a credit balance. It had also been able to introduce several scientific departments. It was the intention to utilise the institution during the coming year for the benefit of the public more than had ever been done. The Government had been good enough to advance £6000 to provide for certain much needed improvements and the board intended to enlarge the operating theatre and to bring it up to modern requirements. It was also intended to afford greater facilities for treating casualty cases. The board, in conjunction with the University of Sydney, was making the necessary arrangements to give better education in connexion with the School of Dentistry which it was expected would be established before long at the Sydney Hospital. At the ordinary monthly meeting of the board of directors a request was granted from the honorary medical staff for permission to erect a tablet at the hospital in memory of the late Dr. Neill. Dr. O. V. Bowker was appointed medical superintendent, Dr. H. S. Stacy resident pathologist, and Dr. A. G. Corbin, senior resident medical officer.

Prince Alfred Hospital, Sydney.

The annual meeting of the governors of the Prince Alfred Hospital, Sydney, was held on March 6th. His Excellency the Lieutenant-Governor presided. The report for 1900 stated that the number of patients under treatment during the year and the general results were as follows. Remaining in hospital Dec. 31st, 1899, 219; admitted during the year 1900, 3287—total under treatment, 3506. Of these 1807 were cured, 782 were relieved, 313 were unrelieved, 381 died, and 223 remained in hospital on Dec. 31st, 1900. The number of beds in the hospital was 236; average number resident daily, 227; mean residence of patients in days, 27; rate of mortality per cent. (deducting the 58 deaths of patients which occurred within 24 hours of admission), 9·21; rate of mortality per cent. over total cases under treatment, 10 7; rate of mortality per cent. on admissions, 11 59. Number of attendances in out-patient and casualty departments, 43,769; number of individual patients in these departments, approximately, 11,000. Of the patients admitted during the year 1148 were cases of accident or urgency, 1420 were received under Government vouchers, 712 contributed more or less towards their support in the hospital, and 32 were treated in the Ogilvie and Fairfax wards (included in contributing cases) The total amount received from contributing patients during the year was £2201 14*s*. 3*d*. The mean residence in the hospital of each patient during the year had been 27 days. Of the total deaths occurring in the hospital 58 took place within 24 hours of admission. The average cost per bed for the year had amounted to £66 7*s*. 6*d*., as against £69 16*s*. 9*d*. in 1899 This result had been calculated, as in past years, after deducting the cost of the out-patient department, and of buildings and permanent improvements, from the total expenditure. The income for the year was £17,602 3*s*. 3*d* £506 2*s*. of this amount were transferred from the endowment fund to cover the cost of building the ambulance-driver's cottage. The Government contributed £10,092 3*s* 9*d*., £3800 12*s*. 5*d*. on the £ for £ principle, and the remainder for the maintenance of Government patients. Professor Anderson Stuart, president of the hospital, said that the operative department of the hospital had been an increasing one. In 1883, when the hospital was opened, there were *only 147 operations. Last year there were no* less than 1733. This showed the growth in the amount of work done in the hospital. The accommodation was altogether too limited. They had 236 registered beds in the hospital. The average number of persons in the hospital had been about 227, leaving only nine beds for the whole hospital, as on the average, available at any given time. But that did not really represent the actual state of affairs. Taking this year as far as it has gone, there had only been nine days when they had a number of patients in the hospital equal to, or under, the number of beds in the hospital. On every day of this year, excepting those nine days, there had been more patients than beds. They put patients in shakedowns and on the floor, and then they were simply obliged to say, "We are sorry, but we cannot take a case in." They had been obliged to do that in cases that ought to have been taken in. Absolutely the accommodation of the hospital and the resources of the hospital were fully occupied, and they simply could do no more. That meant that evidently the time had come when the resources of the hospital would have to be increased. The following appointments have been made at the hospital: medical superintendent, Dr. C. B. Blackburn; resident pathologist, Dr. J B Cleland; resident anæsthetist and registrar, Dr. W. E Harris; resident medical officers, Mr. E. V. Barling, Dr. J. a'B. D. Barton, Dr. R. D. Heggeton, Dr. Sydney Jones, Dr. A. H. Macintosh, and Dr. S. M. Verco; gynæcological clinical assistants in the out-patient department, Dr. A. Watson Munro and Dr. H. C. Taylor Young.

March 19th.

Obituary.

JOHN ARCHIBALD LORIMER, M.R.C.S. ENG., L.R C P. LOND.

THE death occurred on April 27th, at Farnham, of Mr. J. A. Lorimer. On April 26th Mr. Lorimer whilst on his professional round was being driven in a governess car by his coachman when the pony got beyond control and bolted, and the vehicle was overturned. The coachman escaped unhurt but Mr. Lorimer received serious injuries. He was removed by members of the local ambulance association to his home in Castle-street, where he was seen by Dr. C. E Tanner and Dr. J. Hussey, who found that there was but slight hope of his recovery, the base of the skull being fractured; he had also a badly fractured arm He remained unconscious until Saturday afternoon, when he died. Mr. Lorimer was 54 years old and he enjoyed an extensive practice in Farnham and neighbourhood for upwards of 30 years. At the time of his death he was medical officer to the rural sanitary authority of Farnham, medical officer to the Farnham Joint Isolation Hospital, medical officer of the Farnham and Hartley Wintney School District, and medical officer of the north district of the parish of Farnham. Mr. Lorimer had always taken an active part in public affairs and was a member of the Farnham School Board. Formerly a Liberal in politics, he joined the Unionist party at the time of the Home Rule split. He has since been a warm supporter of the Right Honourable St John Brodrick, M P., and as local chairman of his committee at the election last year contributed largely to the return of the Secretary of State for War. He was exceedingly popular and his death is universally mourned in West Surrey.

MEDICAL MISSIONARY ASSOCIATION.—The annual meeting of the friends of the Medical Missionary Association was held at Exeter Hall on April 26th, Dr. George Saunders, C.B , presiding. The report for the past year stated that during the past winter nine men had been in residence in the training house at Highbury-park. Dr. J L. Maxwell said that the association encouraged its students to take the highest possible training, and this was not found prejudicial to the missionary spirit and activity. The year's receipts have been £1761 and the expenditure £1857.

Medical News.

University of Cambridge.—At the congregation on April 25th the following degrees were conferred:—

Doctor of Medicine.—C. Woodhouse, King's College; W. Langdon Brown, St. John's College; and A. E. Porter, Emmanuel College.
Bachelor of Medicine and Bachelor of Surgery.—C. C. Simpson, Trinity College; and H. A. Upward, Christ's College.

The following have passed the examination in Public Health for the University diploma:—

S. H. Ali, J. B. Anderson, J. Andrew, J. M. Flavelle, J. G. Forbes, J. C. Harcourt, T. H. Jones, R. H. Makgill, H. de R. Morgan, R. Niven, A. C. Pearson, H. Peet, H. M Pereira, W. H. Read, S. T. Reid, H. A Schölberg, S. W. Thompstone, W. B. Thomson, F. C. Tothill, J. C. White, and D H. Williams.

Mr. Edmund Owen has been appointed an additional examiner in surgery.—There are over 90 candidates for the Easter term examination in surgery and midwifery.—Tenders for the erection of the Medical School and Humphry Museum have been received. They amount to about £26,000 and their acceptance by the University is recommended by the building syndicate.—A studentship for research in botany will be vacant at Michaelmas in Caius College. Candidates must be Bachelors of Arts who have taken honours in the Natural Sciences Tripos, Part I. Names are to be sent to the Master of the College by Oct. 1st.

University of Durham.—At the third examination for the degree of Bachelor in Medicine, held in April, the following candidates satisfied the examiners:—

New Regulations—Anthony Bourchier Bradford, St. Thomas's Hospital; John Cooper, B Sc., F.C.S., John Wilfrid Caton, John Frederic Dover, and Guy Rowland East, College of Medicine, Newcastle-upon-Tyne; George Ernest Froggatt, Middlesex Hospital; Charles Wm. Menelaus Hope, College of Medicine, Newcastle-upon-Tyne; Wharram Henry Lamplough, Birmingham University; Charles Robert Lease, College of Medicine, Newcastle-upon-Tyne; Lucy Selina Molony, London School of Medicine for Women; Francis O'Neill, College of Medicine, Newcastle-upon-Tyne; Thomas Eben Pemberton, Birmingham University; Alfred Henry Proctor, College of Medicine, Newcastle-upon-Tyne; Percy Montgomery Rivaz, St. Bartholomew's Hospital; Thomas Rowell, William Greenwell Robson, Frederick William Ritson, and Basil Edward Spurgin, College of Medicine, Newcastle upon-Tyne; Charles Ravenscroft Stewart, St. George's Hospital; and Godfrey de Bec Turtle, King's College Hospital.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—At the spring sittings of the Triple Qualification Board of the Royal Colleges of Physicians and Surgeons of Glasgow held in Glasgow the following candidates passed the examinations as indicated:—

First Examination (five years' course).—Alexander Robb M'Intyre MacIlraith, William MacIlraith, John Watt, and Thomas Ormiston Wilson, Anderson's College Medical School; Hugh Graham Anderson, Kenneth James Logan Bannerman, William Watkin Neilson Knox, Ernest Adolphus Neal, and Joseph Lloyd Owen, St. Mungo's College; Stewart Ashwood Friar, Queen's College, Belfast; John Austin Joseph Crowley, Queen's College, Cork; James Augustus Robertson and William Frederick Clarke Walker, Royal Colleges, Edinburgh; and William Frederick Fismer Durr, University of Edinburgh.
First Examination (four years' course)—Morgan Evans Jones, Edinburgh School.
Second Examination (five years' course).—Katharine Mary Chapman, Queen Margaret College; John Priestley Newton and James Robert Robertson, St. Mungo's College; John Hutchison Fyfe and Edward Graham Taylor, Anderson's College; David Ahern, Queen's College, Cork; Emily Jane Polito, London School of Medicine for Women; Edward Percy Airth Richardson, School of Physic, Dublin; and James Cullen, Edinburgh University.
Second Examination (four years' course).—A. W. Macdonald, Glasgow University; and Lewis Edward Jarrett, Anderson's and Owens Colleges.
Third Examination.—Henry Rayner Helsby (with distinction), William George Macdonald, Thomas Joseph M'Kagney, Richard Lewis, Stanley Lister George D. Maclaine and Peter Carruthers Watt, St Mungo's College; David Moodie, Anderson's College; Hermann S. Christoffelsz and Hamilton Watson, Royal Colleges, Edinburgh; Gordon Stonehouse and William Dalziel Sutherland, Durham University College, Herbert Macmaster, Queen's College, Belfast; and Marion Ethel Unwin, London School of Medicine for Women.
Final Examination (and admitted Licentiates of the three coöperating authorities)—Stewart Jackson Farries, St. Mungo's College; George Russell Jarvie, Anderson's and St. Mungo's Colleges, John Blair Conner, Anderson's College; Angus MacLeod, Anderson's College and Edinburgh University; Shusil Kumar Roy, Glasgow University and Anderson's College; William Parsons Lappin, Dublin and Edinburgh Schools; James Herbert Spray, Yorkshire College, Leeds; Robert John Morgan, Queen's College, Belfast; Gordon Stonehouse and Joseph Edwin Cooper, Durham University Medical College; John Stewart, University of Glasgow; and John Joseph Minihan, Queen's College, Cork.

Royal University of Ireland.—The examiners have recommended that the following candidates be adjudged to have passed the under-mentioned examinations respectively:—

M.B., B.Ch., B.A.O. Degrees Examination.—Upper pass: Joseph G. Anderson, Queen's Colleges, Galway and Belfast; *Michael Curran, M.A., Roman Catholic University School of Medicine; *John P. Harold, Charing Cross Hospital, London; Archibald G. Heron, B.A., Queen's College, Belfast; *William M. P. Keogh, Roman Catholic University School of Medicine; Patrick Kerley, Roman Catholic University School of Medicine; John C. M'Carroll, Queen's College, Belfast, and Middlesex Hospital, London; *David M'Mordie, B.A., Queen's College, Belfast; *John O'Leary, Queen's College, Cork; and * John A. D. Radcliffe, Queen's College, Belfast.—*Pass:* Marion B. Andrews and William Barkley, Queen's College, Belfast; William C. Gavin, James Gorman, and Timothy J. Hartigan, Roman Catholic University School of Medicine; Robert Kennedy and Thomas Kennedy, Queen's College, Belfast; Michael J. M'Donough, Roman Catholic University School of Medicine; John M'Murray, Queen's College, Belfast; Peter G. Moran, Roman Catholic University School of Medicine; Chesnut Peacock, Queen's College, Belfast; Andrew J. Quirk, Roman Catholic University School of Medicine; Ernest F. Scott, Queen's College, Galway, and Edinburgh School of Medicine; and Hugh B. Smith, Queen's College, Belfast, and Middlesex Hospital, London.

The candidates marked thus * may present themselves for the further examination for honours.

M.D. Degree Examination.—Patrick T. O'Sullivan, M.B., B Ch., B.A.O., Queen's College, Cork, and private study; and Richard S. Ryce, M.B., B Ch., B.A.O., private study.

Doubtful Pickles.—A pickle and jam manufacturer of Exeter was prosecuted by the City Council on April 22nd for having in his possession for sale as food half a cask of red cabbage which was mouldy and rotten, some onions which were unfit for use, and six dozen bottles of pickles which were mildewed and stinking. The magistrates thought that the case was a proper one to bring forward, but the defendant was discharged as there was a doubt whether the articles in question were intended for food.

The Birmingham General Hospital and Sir John Holder—The Board of Management of the Birmingham General Hospital has recently decided that a portrait of Sir John Holder shall be painted in order to commemorate his services to the institution Sir John Holder is chairman of the Building Committee, by whose exertions the new general hospital was erected at a cost of over £200,000. A replica of the portrait is to be presented to Lady Holder. It is intended that the presentation shall be from those only who are interested in the hospital. The new building was opened free from debt in 1897 by Princess Christian.

Medical Fees.—At the St. Austell (Cornwall) County Court on April 23rd Mr. R. F. Stephens, M.R.C.S. Eng, L.S.A., sought to recover £18 from a man residing at Pentewan for professional services. Defendant admitted having had a long illness, but said that other members of the family were included in the account. His Honour Judge Granger said that there had not been the slightest attempt to pay the money, the fact being that some people thought that a medical man was the last person to be paid, and that because he was unwilling to sue them they could thus avoid the debt. An order was made for the payment of £16.

Sanitation in Rural Devonshire.—Mr. S. Noy Scott in his annual report for 1900 as medical officer of health of the Plympton (Devon) Rural District Council states that the majority of the cottages and isolated houses are provided with closets over cesspits. He frequently finds an owner willing to abolish a cesspit, but the occupier raises all sorts of objections which are sometimes so strong as to prevent the closet being used after it is erected. It is by no means uncommon for the earth-closet to be converted into a toolshed, storehouse, or used entirely as a wash-house. Mr. Noy Scott considers the earth-closet worked on the bucket system to be the best method of excrement disposal for isolated cottages in a rural district.

Freemasonry: *Æsculapius Lodge, No. 2410.*—The last meeting for the present Masonic year was held at the Hotel Cecil, Strand, on April 24th, Bro. Montague Cheale, M.R.C.S. Eng., D.P.H. Cantab., the Worshipful Master, being in the chair. Bro. Ernest Clarke, M.D. Lond., F R.C S. Eng., was unanimously elected Worshipful Master for the ensuing year. Bro. G. Danford Thomas, M.D. Brux., Coroner for London and Middlesex, was re-elected Treasurer, and Bro. Thomas Dutton, M.D. Durb., M.R C.P. Edin., was reappointed Secretary. The Secretary was instructed to send a letter of congratulation to Bro. Captain Percy J. Probyn, R.A.M.C., D.S.O., and Bro. W. Washbourn, M D., C.B., on the very distinguished and gallant services which they have rendered to their country in South Africa. Five guineas were voted to the British Medical Benevolent Fund. After all business had been transacted the lodge was closed. 33 of the members afterwards dined together.

CHORLEY JOINT HOSPITAL.—Mrs. Ainsworth of Rivington opened on April 27th a new hospital for infectious diseases at Heath Charnock. It has cost £17,000. The Chorley Corporation, the Adlington and Leyland District Council, and the Rural District Council have contributed towards this outlay. The hospital contains accommodation for 36 beds and is well situated.

HIS MAJESTY THE KING has consented to become the patron of the Church of England Temperance Society.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Military Drill for Boys and Youths.

The House of Lords has given its assent to the second reading of the Bill approved by the Headmasters' Conference for providing for boys and youths attending school a certain amount of military drill The representatives of the Government, while allowing the stage to be taken unchallenged, intimated that the measure will have to be submitted to rigid examination by the responsible departments. It may therefore be taken that the Bill will not be allowed to pass, at any rate in its present orm.

Isolation Hospitals Bill.

This important measure, which is designed mainly for the encouragement of isolation hospitals, has passed through the Grand Committee of the House of Commons on Law. Its provisions enable local authorities who have provided hospitals to transfer them, with the sanction of the Local Government Board, to county councils, and further authorise the latter bodies, again with the sanction of the Local Government Board, to make annual contributions towards the *maintenance or* extension of hospitals in the hands of local authorities The question of giving county councils power to lease hospitals was raised in the Grand Committee, and the President of the Local Government Board undertook to consider the matter before the report stage of the Bill. Mr. Long accepted an amendment enabling county councils to contribute to hospitals outside their area of jurisdiction. Some argument arose on the requirement of the consent of the Local Government Board as a condition of contribution by the county councils. Mr Long explained that this requirement is really in the interests of county councils, because, as he said, great pressure may *be brought to bear upon these bodies to contribute* to hospitals which are of an unsatisfactory character. He had taken the advice of the chief medical officer of the department on the *subject, who thought it* was absolutely necessary, in the interest of the public health, to have this requirement. Sir Walter Foster expressed his *concurrence in this* view and the Grand Committee decided to retain the requirement.

HOUSE OF COMMONS.

THURSDAY, APRIL 25TH.

Plague at the Cape.

[illegible] State for the Colonies whether [illegible] now raging in Cape Town and [illegible] ortions; whether the statistics *published of those* who had taken *this disease* and of those to whom it had proved fatal were confined to cases in Cape Town itself, and whether he could state the numbers in Cape Colony who had been affected with and who had succumbed to this disease and whether he [illegible]

with persons or things on board from which danger of infection is apprehended *Special* memoranda prepared by the medical officer of the Local Government Board with respect to plague have been issued to the local authorities and such further advice and instructions as may from time to time be found requisite will be issued to them. Where exceptional circumstances render it expedient it is my practice to send a medical inspector to confer with the port authorities and their officers I can assure the hon. Member that everything that can be done will be done to prevent the possibility of the spread of the disease.

FRIDAY, APRIL 26TH

Small pox in Lisburn.

Mr DALY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that a serious outbreak of small pox had [illegible] enforced.

MONDAY, APRIL 29TH.

Small pox Precautions.

Sir JOHN LENG asked the Lord Advocate whether he would take steps to prevent manure being sent from Glasgow, where for months past small-pox had been prevalent, for distribution in the county of Fife from railway stations in burghs which held clean bills of health, or whether he would point out to the local authorities what means they could take to prevent the risk of spreading small pox by such distribution.—The LORD ADVOCATE replied: Unless there is a legal warrant for the assumptions made by the hon Member in the question which would require specific proof of injury or danger to health there exist no statutory powers under which such distribution can be prevented, having in view the judicial interpretation which has been put upon the provisions of Section 16, Sub section 5, of the Public Health Act, 1897.

Water Purchase Schemes.

Mr. PARKER asked the President of the Local Government Board whether the Government would consider favourably a proposal to authorise local authorities to compel water companies to sell their [illegible] answer to the first part of the question must be in the negative. Death Certification in Scotland.

Mr. WEIR asked the Lord Advocate having regard to the fact that in [illegible] not at present proposed to undertake.

Medical Practitioners and the Royal Naval Reserve.

Captain JESSEL asked the Secretary to the Admiralty if he would explain why the privilege of serving in the Royal Naval Reserve was denied to medical practitioners, and whether, in view of the duties which the surgeons of the royal navy would have to undertake in time of war, h[illegible] medical branch of the R[illegible] replied: This question [illegible] ralty on several occasions [illegible] form a medical branch of [illegible] be met by the entry of [illegible] cial regulations have been [illegible] universities and medical schools

HOURS OF LABOUR IN SHOPS.

EVIDENCE FROM SIR WILLIAM S. CHURCH AND SIR WILLIAM MAC CORMAC

On April 29th, Sir WILLIAM S CHURCH, President of the Royal College of Physicians of London, gave evidence before the Select [illegible] opinion of the committee such hours were injurious to health and in many cases, especially among women, caused illness. The then President of the Royal College of Physicians of London issued a circular to the me[illegible] consequence of this circular more [illegible] petition declaring the hours to be in[illegible] House of Commons to pass into law [illegible] by Sir John Lubbock (now Lord Ave[illegible] learned in evidence that these long [illegible] had been increased, and he wished to know from Sir William Church whether he concurred in the views of these 300 medical men that such hours were grievously injurious to health.—Sir WILLIAM CHURCH replied that it was self evident that 14 hours per day of confinement in a shop must be prejudicial to those exposed to it. He was not sufficiently acquainted with the subject to know how far it was possible or desirable that individual labour should be controlled by the State and he should therefore desire to confine himself to the medical aspects of the case. He was strongly of opinion that the present long hours in shops were injurious to health.—In reply to the Earl of HARDWICKE, Sir WILLIAM CHURCH said that he was not sufficiently acquainted with the subject to express an opinion on Lord Avebury's Bill for the earlier closing of shops. There were other things besides the hours of labour to consider. For instance, there was the condition of the buildings, their ventilation, and other matters which he thought might be regulated rather than that the State should intervene and set a particular hour at which closing should take place. It had occurred to him that in the case of small shops, say in provincial towns, the business was managed by members of the family who were not continually in the shop throughout the hours of opening. To lay down a hard-and-fast law as to closing might be rather harsh upon the occupiers of such shops. But, of course, it was merely an opinion.—The CHAIRMAN explained to Sir William Church that in his Bill the hours of closing were left to the decision of the majority of the local shopkeepers and were not laid down by enactment, and further that it had been brought out in evidence that the small shopkeepers were themselves anxious for some measure of the kind.—Sir WILLIAM CHURCH, in answer to the CHAIRMAN, said that he had no hesitation in expressing to the committee his opinion that there were certain forms of weakness and disease which were extremely aggravated by long hours of more or less—not sedentary but not active—employment. This was especially the case when the shops were lighted by gas. The evil was not merely the presence in the shop, but the absence of opportunities for getting fresh air and exercise.—In reply to the Bishop of WINCHESTER, Sir WILLIAM CHURCH said that there were two great classes of ailments which were aggravated by work like that of shop assistants. There was the class which came within the cognisance of surgeons, and those physicians who practised more especially among the diseases of women. But there was another great group which fell to the ordinary physician and of which they saw a great deal in the London hospitals—that was the anæmic condition produced partly by the long hours and still more by the confinement which such an employment as that of a shop assistant entailed. These patients did not get sufficient opportunity of being in the fresh air and sunlight, and their condition was greatly aggravated by late hours at night. It was the confinement rather than the labour which caused the mischief. Personally he had not paid much attention to the question of legislation, but he should not have thought that the necessity was greater than in the case of other workers, such as clerks and people of that sort, in the big towns. He was, however, only speaking of the evils produced from confinement in a more or less contaminated atmosphere, and he said that the detriment to the shop assistants was very much akin to the detriment which fell upon other workers. Of course, the longer the hours the greater the detriment.

At the same sitting of the Committee Sir WILLIAM MAC CORMAC, President of the Royal College of Surgeons of England, was examined. His evidence was to the effect that such long hours of labour in shops as had been brought to the notice of the Committee tended very much to lower the vitality of the workers and rendered them more liable than they otherwise would be to attacks of different forms of disease. The night hours were spent in an atmosphere very prejudicial to health, an atmosphere which contributed largely to the production of various forms of tubercle. He held strongly the opinion that moral and physical well-being depended largely upon one another. If the physical condition of a man or woman was affected, the moral nature must also suffer to some extent. He was of opinion that this subject was worthy of the attention of the Government and of Parliament all the more because, although it could not be said in one sense to be urgent, the evil was insidious, gradual, and progressive in its effect. From generation to generation the population would become feebler if the evil were not resisted. The question of the work being a strain was not the point, but rather the conditions in which the work was carried on.

ROYAL COMMISSION ON ARSENICAL POISONING.

FRIDAY, APRIL 26TH.

THE Royal Commission on Arsenical Poisoning resumed its sittings in London to-day and examined a number of witnesses. The members of the Commission are Lord Kelvin (Chairman), Sir William Hart Dyke, M.P., Sir William S. Church, Professor Thorpe, Dr. Whitelegge, and Mr. Cosmo Bonsor, with Dr. G. S. Buchanan as secretary.

Mr. HENRY A. TAYLOR, of Messrs. H. A. and D. Taylor, maltsters, Ware and Bishop Stortford, gave evidence as to the processes of malt-making. He expressed some objection to the habit of brushing malt, his view being that it gave an artificial value and made mouldy malt look as well as good malt. His firm, he said, used only anthracite coal, and from the results of analysis he gathered that the best anthracite coal contained little or no arsenic. He did not think, however, that anyone could guarantee any coal to be absolutely free from arsenic, and if the coal could not be guaranteed neither could the malt made with it.

Mr. CORNELIUS O'SULLIVAN, chief brewer and chemist to Messrs. Bass, Ratcliff, and Gretton, Burton, was the next witness, and in the course of his examination he said that when it became known, through the daily pap[illegible] about Nov. 23rd last, that arsenic was found in some beers [illegible] source whence it was derived was clearly indicated, [illegible] able as a precautionary measure by the Burton [illegible] doubt, with the brewers all over the country, [illegible] which arsenic could be introduced into beer [illegible] ned, and as the sugars of different kinds em[illegible] were the sources chiefly implicated, at least to begin with, the use of these was discontinued in most cases at once, although examinations had since shown the precaution unnecessary; the sugars, as a rule, had been found free from arsenic, or at least practically so. Further, it was considered desirable that all beers in stock should be examined by the local staffs and by outside authorities. Burton brewers had, as a rule, competent chemists on their staff, and those who had not employed such men outside. The general results were that the beers were declared practically free from arsenic. But when developments took place and when the academical side of the question took the place of the practical one it was found that there was yet something to learn as to the presence of minute quantities of arsenic in beer and as to the sources thereof. It was observed that in some of the beers these minute quantities of arsenic were greater than in others. The cause of this was inquired into and it was soon established that malts dried with a proportion of gas-coke contained much more arsenic than malts dried with a proportion of oven-coke. These facts were confirmed by outside observation. The use of these malts was at once discontinued and as a further precautionary measure even oven-coke was as a rule discarded and the cleanest anthracite alone employed. For many years Burton brewers had used little or no gas-coke, for the simple reason that it imparted a smoky disagreeable flavour to the malt, which was carried to the beer. Of course, as far as practicable, they bought no such malt. But inasmuch as outside maltsters recognised this fact care was taken by them to eliminate the flavour by selecting the gas-coke they employed, so that in most cases it was impossible from the odour alone to distinguish gas-coke dried malt from any other. It appeared, however, that the selection of the non-flavour-giving varieties of gas coke did not also eliminate the arsenic-containing ones. Hence it was deemed desirable to discontinue the use of all outside malts until they were tested and found to be practically free from arsenic. All these precautions notwithstanding, it was still observed that all the beers were not absolutely free from arsenic when the rigorous test was applied; quantities varying between 1-100th to 1-500th grain per gallon and practical purity were certified to by competent authorities. He might mention, as an example, that he had had examined by a leading authority, with whom his own observations were in broad agreement, 32 samples of different beers, the products of some of the chief breweries of England, Ireland, and Scotland, and of Holland, with the results that they were found to contain quantities of arsenic trioxide varying between 1 50th of a grain per gallon and practically *nil*. The *nil* samples amounted to three in the 32, and he believed two of these were part sugar beers, or beers brewed with part grits, made from flaked maize or rice. This being the case the cause of it and the means of obviating it had to be sought for. An examination of malt dust—i.e., the dust obtained on screening and fanning the malt after the grosser rootlets had been eliminated—showed that it contained much more arsenic than the malt itself; hence it had been decided to put up apparatus containing brushes and screens of the highest efficiency. They would still further reduce the infinitesimal quantities of arsenic in beers, but he could not hope that they would be thereby absolutely eliminated. Hops had also been carefully examined and although many growths had to be rejected in consequence of the large quantity of free sulphur they contained, very few samples had been found to contain arsenic—in fact, they might so far be said to be absolutely free. As, however, sulphur washes were used during their growth, as they were frequently treated with free sulphur when maturing, and as sulphur was used in kiln fires during drying, it would not be surprising if hops, too, were on investigation found to supply their quota, however small, of arsenic to beers. This was also a contingency against which brewers would, of course, have to guard. He had indicated the precautions taken which were considered desirable with the view of eliminating the [illegible] even minute quantities of arsenic into beers and [illegible] expected. All the precautions take[illegible] but he could not say that they had so far effected complete elimination in all cases. He believed it could be shown that beer must have contained minute quantities of arsenic from time immemorial, but he believed there was no evidence that any effects injurious to health attributable to this quantity of arsenic had so far been recorded. Methods for the detection of arsenic in beer were given in analysts' books, but it was fairly clear that this arsenic was supposed to be introduced by accident or malicious intent. He did not wish to deal with the methods of determination of minute quantities of arsenic, but he must say that he believed that they were in some hands broadly satisfactory as far as they went. He was, however, strongly of opinion that this matter should be treated as the Water Commission treated the pure water question—that was, institute an inquiry into the matter with Governmental authority so that practical methods might be establishe[illegible] ensured.

Stonehouse and Joseph Edw

Sir T. [illegible] made a statement to the Commissioners which will be found on page 1257.

In reply to questions addressed to him by Sir WILLIAM CHURCH, Sir T. LAUDER BRUNTON said that while as a general rule women could take less arsenic than men it might be in the case of the Manchester epidemic that the women consumed more beer than the men did and perhaps were always supplied with the same kind of beer. It was possible, too, that the greater physical labour of the men led in their case to more rapid elimination of the arsenic. Asked whether anything had occurred to him as explaining the delay of the medical profession generally in recognising that this disease was due to arsenical p[illegible] to alcohol or other poisoning, Sir T Lauder Brunton [illegible] be their familiarity with cases of neurit[illegible] with alcohol and nothing else. He once came across rather a curious observation in regard to different kinds of wines. It was made to him by the landlord of a hotel above Montreux and it was to the effect that the people in the Rhone Valley who drank the white wine became affected with tremors, whereas the people who drank the red wine in the same locality did not suffer in the same way. It was suggested to him that the white wine was often more or less sweetened with glycerine and that the glycerine might contain arsenic, and these people who drank the white wine might really be suffering from arsenical tremors. With regard to guarantees of purity he thought that practically what was wanted in this country was something analogous to the Gesundheitsrath in Germany—something in the nature of a Board of Public Health. This board should have at least one member thoroughly acquainted with the management of public health, a thoroughly trained chemist, a bacteriologist, a pharmacologist, and a medical man. Probably it would be well to have two representatives of each branch. It would be a board of reference and he supposed would come into relations with the Local Government Board.

By Professor THORPE: If such a board, after taking such evidence [illegible] such questions should be referred.

By Dr. WHITELEGGE: He had been told that British barley contained a much larger quantity of nitrogenous substances than foreign barley, and that if malt were made with British barley without the addition of glucose to counterbalance the nitrogenous matter they were bound to have a very heavy beer.

The Commission then adjourned.

SATURDAY, APRIL 27TH.

The Commission met again to-day and examined several more witnesses

Mr. RICHARD CHARLES GARTON, of Messrs. Garton, Hill, and Co., brewing-sugar manufacturers, Battersea, said that his father, who [illegible] first to introduce into this country [illegible] that at the present time the firm [illegible] brewing sugars manufactured in this country. In time the firm began the making of glucose and afterwards of a brewing sugar known as dextrin maltose. These three articles were produced by the action of sulphuric acid either on cane sugar or starch, the sulphuric acid used being in all cases wholly removed as soon as the action had proceeded far enough by being neutralised by the addition of a base [illegible] insoluble compound. The [illegible] phuric acid. The propor- [illegible] ane sugar varied from ¼ to [illegible] in the raw sugar. As to [illegible] conversion depended upon [illegible] of the starchy material employed. It would require from 4½ per cent. in the case of starch made from maize up to 8 per cent. for sago and tapioca flour. The average percentage of acid used by his firm in the making of glucose was 6½ per cent. The dextrin-maltose was substantially a glucose and was made in the same way, the only difference being that the time allowed for the operation was less. At the commencement the firm only used brimstone acid because the liability of pyrites acid to contain arsenic was, of course, well known to them as to every manufacturer who used sulphuric acid for any purpose [illegible] their sulphuric acid suggested that [illegible] acid, showing them that it was as pure as brimstone acid. They satisfied themselves by means of careful investigation that this was so and the firm in question were allowed to supply purified pyrites acid which they had repeatedly guaranteed to be free from arsenic. Witness had perfect confidence in this firm, but his own firm still thought it right to keep a check on the supply by examining every barge-load of acid and periodically testing for each specific impurity. The difference between sulphuric acid free from arsenic and not free from it was so well known to every manufacturer of the acid, or user, that when dealing with a firm of good standing [illegible] with th[illegible] were in[illegible] substitutes for better material. One or other of them was used by all the best brewers in the kingdom after [illegible] maltose which was formed in the mash tun and by an equally pure process. They were sugars of the same type as the maltose and in every sense as suitable for the purpose. But they had the great advantage that they could be made free from those types of nitrogenous matter found in barley malt which constituted one of the greatest difficulties in brewing English beer, their removal necessitating prolonged storage of the beer and the employment of much hop. It thus put a definite material in the hands of the scientific brewer by which he could obtain complete control over the article produced. With regard to the invert sugar, it was a far more expensive article for the brewer than the cane sugar itself, and the whole manufacture was for the purpose of giving him a more readily fermentable sugar than cane sugar, which cannot be employed without materially weakening the yeast. So important were those properties that all modern ale required their use. As compared with malt there was no economy in the use of invert, as a pound of extract obtained from invert was about the same cost as that obtained from malt and yet three-quarters of the total production of his firm consisted of this substance. It was for the results of the brewing, and not for lessening the cost of the materials, that it was employed.

Dr THORNE, chemist to Messrs. Garton, Hill, and Co., stated, in reply to Sir William Church, that he had never found selenium in [illegible] s of it in brimstone [illegible] selenium in pyrites [illegible]

[illegible] the Mill-road Infir[illegible]pool, and consulting physician to the West Derby Union Workhouse, said that the recent epidemic of arsenical poisoning in Liverpool did not seem to have been so extensive as in Manchester, although some of the cases had been of a severe type. During the last three years, out of 12,823 patients admitted into Mill-road Infirmary under his care there had been 226 cases of peripheral neuritis, of which number 153 had presented symptoms which might be attributed to arsenic. Of these 226 cases of peripheral neuritis 51 died, the apparent cause of death being general asthenia, with cardiac failure in most of the cases. Witness presented a table showing the number of cases of [illegible] '98, 1899, 1900, and [illegible] '98 there were 20 cases; in 1899, 54; in 1900, 143; and in the period of 1901, 23 cases. Reviewing the epidemic as a whole and after very careful observation he had noticed th[illegible] Th[illegible] the [illegible] dif[illegible] cas[illegible] ac[illegible] ac[illegible] rec[illegible] recorded. 2.—The chronic cases. These formed by far the greater number, and on admission presented the usual symptoms of peripheral neuritis and had the appearance of some slow and chronic form of poisoning attributed at that time to alcohol. Although he had been in the habit of seeing cases of alcoholic neuritis for the last 15 years he had not noticed any difference in the character of the symptoms in patients admitted into this infirmary until the beginning of August, when a few of the patients showed well-marked general pigmentation of the skin, which for want of a better diagnosis was attributed to Addison's disease. During the next three months six cases were diagnosed as Addison's disease, although it was felt at the time that the cases were not typical of that affection. Of these six cases three died and on post-mortem examination no evidences whatever were found to confirm the diagnosis of Addison's disease, on the contrary, the cause of death seemed to be alcoholic neuritis. It was not until the paper of Dr. Reynolds appeared at the end of November that his attention was directed to arsenic, and then, of course, the epidemic was explained and steps were at once taken to prevent its spread. With regard to the cause of alcoholic neuritis he was convinced, from a very careful observation of a very large number of cases, that beer and porter were the general drinks consumed, by far the greater number being due to beer alone, but he had certainly seen cases of undoubted alcoholic neuritis in which the patients had only taken brandy or whisky. With regard to this point his experience whilst in charge of a large Scotch hospital for four years was of interest, as during the whole of that time he only saw four cases of peripheral alcoholic neuritis, and it was well known that the popular drink in Scotland was whisky. He believed also that the serious lesions were caused by the continual drinking of moderate quantities every day for l[illegible] sudden outbursts where large quan[illegible]creted. The great majority of cases [illegible]urred amongst women of the poorer classes, and in Liverpool it was the custom for these women to congregate in each other's houses and send for cheap beer during the whole of the day. By consuming it off the premises they got what was called "the long pull," which meant that they got a good deal more beer than they asked for. In some of the samples of beer examined by the public analyst of Liverpool as much as one and a half grains of arsenic to the gallon were found. This, of course, was an extreme amount, and the general adulteration varied from one-thirtieth grain to one-tenth grain of arsenic per gallon. In one particular case of acute arsenical poisoning a man who had previously been a teetotaler for six months drank 42 pints of beer in two days. On the second day afterwards he was seized with all the symptoms of acute poisoning, and on admission to hospital was very seriously ill. On examination of his urine arsenic was found in large [illegible] rapidly and within a fortnigh[illegible]is was an example of a larg[illegible] into the system in a short p[illegible] the cases small quantities of arsenic had been taken spread over a prolonged period. In many cases patients would only admit to having taken small quan[illegible] had been [illegible] not neces[illegible] points whi[illegible]

By Dr. W[illegible] fatal. In some of the cases the paralysis apparently was permanent, at any rate, it was very inveterate and had not yet shown any improvement

By the CHAIRMAN: In his opinion, arsenic accentuated to a marked degree the symptoms of alcohol. There were, as it were, two types—one which arose from alcoholic excess and one which was increased in its intensity by the presence of arsenic. Very small quantities of arsenic in beer would produce severe symptoms.

By Sir WILLIAM CHURCH: In the case of the man who had been teetotal for six months and afterwards drank 42 pints of beer in two days the symptoms were gastro-intestinal and sensory, the latter being the most marked. There was no paralysis in his case.

Dr. RAW then went on to say that two kinds of pigmentation were met with in arsenical poisoning—one, which was a general darkening of the whole surface of the body, did not desquamate. This appeared slowly and disappeared very slowly. The other form was one in which the skin became dark in colour rapidly, especially attacking the flexures, the breast, and the front of the abdomen. The epidermis desquamated freely and could be pulled off, leaving a normally coloured skin underneath. The first variety of pigmentation was met with in the earlier part of the epidemic, the second class only towards the end of the epidemic, and to his mind it seemed to suggest some rather serious increase of the contamination of beer. He had noticed in two cases under his care at present a complete relapse of all the symptoms. The patients were apparently well, pain had disappeared, and the desquamation of the skin had been complete when, without any warning, a fresh attack of neuritis developed, as acute as before, with a general discolouration and desquamation of the skin.

By the CHAIRMAN: The relapse took place without more drinking. In both these cases arsenic was found in the urine shortly after admission. The urine was examined at the time of the relapse and no arsenic was found then. [illegible] undoubted cases where the disease was produced entirely by spirits. He had also seen cases of peripheral neuritis caused by the medicinal administration of arsenic in disease; these symptoms, however, had quickly passed off on the cessation of the drug. After a careful observation of the epidemic he had come to the conclusion that the sensory symptoms were more pronounced in arsenical neuritis than in ordinary alcoholic neuritis and, although very severe at first, they soon passed away. The motor symptoms tended more quickly to recovery under treatment than the purely alcoholic cases, and most of his patients had completely recovered, although a few were making little progress. When one considered the enormous number of people who had been drinking this beer, which had in some cases in Liverpool contained one and a half grains of arsenic to the gallon, one was bound to think that some people were more susceptible to arsenic than others, as only a very small proportion had been attacked. It was apparent, too, that arsenic was a cumulative poison to some extent. It would seem also that the action of the arsenic in the system was more virulent in the presence of alcohol than when given alone So far as Liverpool was concerned the epidemic was at an end and he had not had a new case of arsenical poisoning during the last nine weeks. It was just possible that with greater care in the manufacture of beer alcoholic neuritis might become much less frequent and he had noticed that since the epidemic of arsenical poisoning in Liverpool the amount of alcoholism had much decreased, a state of matters which he sincerely hoped would continue.

By the Chairman: His opinion was that the epidemic had given the community of Liverpool a great fright and alcoholism had been reduced in consequence.

By Dr. Whitelegge: He regarded alcoholic neuritis as existing quite apart from arsenic. In his opinion it had reference more to beer and porter than to spirits and he thought that there would be alcoholic neuritis even if there were no arsenic in beer or porter.

By Sir William Church: He could not account for there being more alcoholic neuritis in Liverpool and Manchester than in London, which also had a beer-drinking population. He would not like to express the opinion that the people of Liverpool and Manchester drank more than the people of London.

Mr. George E Davis, chemical engineer, and consulting chemist of the Manchester Technical Laboratory, the last witness examined, gave evidence as to the sulphuric acid industry. Among other things, he said that when the sulphuric acid was sufficiently diluted and kept cool it was possible to eliminate the whole of the arsenic if the operation was properly conducted. Such acid was even better than acid made from brimstone for many purposes, as the sulphuretted hydrogen also purged the acid of its nitrous contents, which were very detrimental in some processes, such as the manufacture of aerated waters and the preparation of some colouring matters.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Annis, E. G., L R.C.P. Lond., M.R.C.S , has been appointed Medical Officer of Health, Borough of Greenwich.

Barron, H. T., M.D. Lond., M.R.C.S., L.R.C.P., has been appointed Clinical Assistant to the Royal Eye Hospital, Southwark, London.

Bowker, G., L R.C.P., L R C.S. Edin., D.P.H. Vict., has been appointed Medical Officer of Health, Sutton Urban District, Surrey, vice E. L. Jacob, resigned.

Bradshaw, Thomas R , B A., M.D. Dubl., M.R.C.P. Lond., has been appointed Consulting Physician to the Samaritan Hospital for Women, Liverpool.

Cairns, L M., M.B , C M. Edin., has been appointed District Medical Officer, Huddersfield Union, vice J. E. Richards, resigned.

Cann, T. P., M.B , B S. Durh., has been appointed Medical Officer of Health, Newhaven Urban District, vice A. G. Mossop, resigned.

Connell, Arthur, M.R.C.S., L.R.C.P. Lond., F.R.C.S. Edin., has been appointed Honorary Surgeon to the Royal Infirmary, Sheffield, vice Arthur Hallam, resigned.

Dawson, W. E , L.R.C P., L.S.A , has been appointed House Surgeon to Victoria Hospital, Worksop (the Dukeries).

Dunn, R. A., M.D. Durh., B.S., L.R C.P. Lond., M.R.C.S , has been appointed Medical Officer of Health, East Herts and Essex Combined Districts, vice J. A. Turner, resigned.

Eames, E. S B , L.R.C.P. Lond., M.R.C.S , has been appointed District Medical Officer, Honiton Union, vice E. F. N. Currey, resigned.

Eglinton, G. W., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health, Wells Rural District, vice J. C. Smyth, resigned.

Evans, D. R. Powell, L R.C.P. Lond., M.R.C.S., L S.A. Lond., has been appointed Public Vaccinator for the North Wimbledon District of the Kingston Union, vice F. W. Parsons, resigned.

Fryer, G. E., L.R.C.P Lond., M.R.C.S., has been appointed Medical Officer of Health, Urmston Rural District.

Galloway, Alexander, L.R.C.P., L.R.C.S Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the South Shields District, South Shields Union.

Gardiner, A., M.B , C.M. Aberd., has been appointed District Medical Officer, Freebridge Lynn Union, vice W. G. R. Macauley, resigned.

Hick, H., L.R C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health, Romney Marsh Rural District.

Hingston, Charles Albert, M.D., B Sc. Lond., M.R.C.S., has been re-appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

Hogan, B., L.S.A., has been appointed District Medical Officer, Poplar Union, vice E. A. Lightburne, deceased.

Hunt, J. W., M.B. Lond., L.R C.P., M.R.C.S., has been appointed Second Assistant Medical Officer to the Somerset Hospital, Cape Town, South Africa.

Hunter, W. L , M.D., B.Ch. Dubl., D.P.H., has been re-appointed Medical Officer of Health, Borough of Pudsey.

Huskie, James, M.B , C.M. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Crosby District of Lancashire.

Ivens, Francis, M.B. Lond., has been appointed Clinical Pathologist and Assistant Pathologist to the Royal Free Hospital, London.

Lister, Thomas D., M.D. Lond., M R.C.P. Lond., F.R.C.S Eng., has been appointed Physician to the City Dispensary, vice Ivens Spriggs, resigned.

Maund, J. H., L.R.C P. Lond., M.R.C.S., has been appointed Medical Officer of Health, Newmarket Urban District, vice W. Hutchinson, resigned.

Montgomery, Sydney H. R., M.B., B.Ch. Irel., has been appointed Medical Superintendent to the West Australian Government's Lunatic Asylum, Fremantle, Western Australia.

Montgomery, W. P., M.B., B.S. Lond , F.R.C.S. Eng., has been appointed Visiting Medical Officer at the Crumpsall Workhouse, Manchester Union.

Moore, P. W., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed District Medical Officer, Shardlow Union, vice W. M. Knipe, resigned.

Nash, J. T. C., M.D. Edin., D.P.H. Cantab., has been appointed Acting Professor of Hygiene at King's College, London, during the absence of Professor Simpson in South Africa.

Perrin, Thos., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer at the Infirmary, Parish of St. Mary, Lambeth, vice R. H. Tompsett.

Price, Frederick W., M.B., C.M. Edin., has been appointed Pathologist to the City of London Hospital for Diseases of the Chest, Victoria-park, E.

REES, J. A., M.B., C.M. Edin., has been appointed District Medical Officer, Aberystwith Union, vice J. E. Hughes, resigned.

ROBERTS, E. G., L.R.C.P., L.R.C.S. Irel., has been appointed District Medical Officer, Anglesey Union, vice W. Thomas, resigned.

SLATTERY, J. B., M.B., Ch.M. Irel., has been appointed Assistant Medical Officer at the Infirmary, Woolwich Union, vice C. C. W. Mays, resigned.

SMITH, R., M.B., C.M. Aberd., D.P.H., has been appointed Medical Officer of Health, Borough of Rawtenstall, vice J. McNaught, deceased.

STURDY, H. C., M.B., B.S., has been appointed Junior House Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, E.

SPROULL, JAMES, M.B., C.M. Glasg., has been appointed Medical Officer of Health, Luddenden Foot Urban District, vice T. Crowther, resigned.

WILLIAMSON, OLIVER K., M.A., M.B., B.C. Cantab., M.R.C.P. Lond., has been appointed Physician to Out-patients to the City of London Hospital for Diseases of the Chest, Victoria-park, E.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £150 the first year and £170 the second year, with furnished rooms, coal, and gas free.

BURY INFIRMARY.—Senior and Junior House Surgeon. Salary, Senior £100, Junior £80, with residence and attendance.

CANCER HOSPITAL, Fulham-road, S.W.—House Surgeon. Salary £70 per annum, with board and residence.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Resident Medical Officer, unmarried. Salary £60 per annum. Also Clinical Assistant for three months, on payment of £8 8s.

CHELTENHAM GENERAL HOSPITAL.—Junior House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £110 per year, with board, apartments, and laundress.

COUNTY ASYLUM, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary £150 per annum, increasing to £250, with board, apartments, and washing.

COUNTY ASYLUM, Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £200, and on promotion to £250, with furnished apartments, board, washing, and attendance.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL.—Medical Tutor. Salary £40 a year.

DERBY BOROUGH ASYLUM.—Assistant Medical Officer. Salary £120 per annum, with board and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Assistant Surgeon.

GENERAL INFIRMARY, Leeds.—Resident Obstetric Officer for six or twelve months. Also House Surgeon for twelve months. Also House Physician for six months. Board, lodging, and washing in each case.

GREAT NORTHERN HOSPITAL, Holloway-road, N.—Casualty Officer for six months with eligibility for re-appointment. Salary at the rate of £52 10s. per annum.

HOLLOWAY AND NORTH ISLINGTON DISPENSARY.—Two Honorary Medical Officers.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

HOSPITAL FOR WOMEN, Soho-square, London, W.—House Physician for six months. Salary £30.

L.R.C.P. Lond., aged 34,

ents and of Mrs. Watson of

Carson-road, West Dulwich,

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CAN A MEDICAL MAN RETIRE FROM A CASE AND CHARGE FOR HIS SERVICES?

AT the Southwark County Court on Tuesday before his Honour, Judge Addison, K.C, Mr. Alfred Matcham of Gladstone-street, S.E., sued Mr. William Lacey of Kennington Park-gardens, to recover £1 10s. 6*d* for professional services rendered. The plaintiff's case was that he attended the defendant's wife and subsequently his child, the latter being ill with bronchitis. The wife was very inexperienced in the care of sick children and she so persistently did what he advised her not to do and refused to do what he requested her to do in regard to the child that after several visits he wrote declining to attend any more and suggesting that another medical man should be called in. His bill for attendance on the wife was 15*s* 6*d*. and that for the child until he gave up the case 15*s*. The defendant declared that only once did his wife rub the child with a liniment which the medical man did not approve of, but when told not to use it she at once desisted. In everything she carried out the instructions to the letter. As the result of the medical attendant's throwing up the case the child, who was suffering from bronchial pneumonia, was without medicine for a whole day and it was not until late at night that the services of another practitioner were secured —His Honour (to the plaintiff)· You cannot recover for attendance on the child. You cannot tell people that you will not attend any more and that they had better call in another doctor and then charge for your own attendances The obligation of a doctor is to attend through an illness as well as he can.—The plaintiff: But the mother persistently refused to follow my advice.—His Honour: You must expect mothers sometimes when they get anxious about their children to rub them with oil or to do things of that kind, but that is not sufficient reason for a doctor to say he will not go on with the case.—The plaintiff But has a doctor no power to retire from a case?—His Honour: Yes; but he cannot charge for it. When you are called into a case your obligation is to do your best until you are discharged.—The plaintiff: But am I not able to charge for services actually rendered?—His Honour: No; they are thrown away where a person has to call in another doctor because you retire on such weak grounds as in this case —The plaintiff: There was such a desire on the part of the mother to go the reverse way to that I wanted her to go and the responsibility rested on me.—His Honour: You are entitled to say you decline the responsibility, and that you will not attend any more, but you cannot charge for your services. There are so many troublesome parents in this world that if a doctor could throw up his case and then charge for it I do not know where we should be. My prejudice is in favour of professional men, but a doctor cannot throw up a case because he feels that his professional feelings are hurt and then charge for it. Your engagement was to attend the child during its illness—that is the ordinary engagement in such a case—and if you throw it up you do it at your own risk. You can only recover for attendance on the wife. Therefore, there is judgment for you for 15*s* 6*d* —Judgment was entered accordingly.

⁂ We do not express any opinion upon this particular case; but it is evident that it would be very unfair if it were to be held a legal principle in all circumstances that a medical man, having once taken charge of a case, can never retire from that charge without sacrificing all fees earned up to the date of his withdrawal.—ED. L.

THE FACTORY GIRLS' COUNTRY HOLIDAY FUND.

WE are requested by Miss M. A. Wyatt, the honorary treasurer of this fund, to acknowledge in our columns a donation of £1 from "A Medical Student."

PREVENTION OF BEDSORES—AIR *VERSUS* WATER.

To the Editors of THE LANCET.

SIRS,—Will you or any of your readers kindly inform me of the relative advantages of the use of air- and water-cushions in preventing bed-sores? I am accustomed to use water, but it is heavy and unpleasant in event of leakage. I am, Sirs, yours faithfully,

April 25th, 1901. W. H. B.

FAIR RIVALRY?

To the Editors of THE LANCET.

SIRS,—May I trouble you to advise me in your next issue, what action I might take, if any, in the following circumstances? Some 10 months ago a practitioner, whom I will call A, came to the village where I practise and took over the practice previously held by another medical man whom I will call B. About 15 months before B left he engaged an assistant who occupied rooms for one year in a cottage in the main thoroughfare between a new estate and the village and station. During the residence of the assistant both B's name and that of the assistant were on a plate at the gate of this cottage. When the assistant left, three months before B, the plate still remained, though B never went near the place. As I had a well-founded belief that B was soon about to leave the village I took no notice of the plate having been allowed to remain on. But when A came in and put his plate on the same cottage gate solely for the purpose of advertising (as he never went to the cottage, which is about 300 yards from where he lives) I thought it was unprofessional conduct. I have made no remark until now, when the cottage changed hands and the present occupier, quite a stranger in the place, refused to have A's plate on the gate. A then put his plate on the gate of another cottage directly facing the main exit from the above-mentioned estate, solely for the purpose of advertising, as I have had some inquiries made and find that he has no rooms in the cottage nor does he dispense there or leave any drugs or medicines there. I think this conduct is advertising, wrong in a professional sense, and very unfair to me. But A has busied himself to do me harm in more ways than one. Amongst others he has called upon a number of my patients, leaving his cards on them, on the ground that he had no formal introduction to the practice from A and did not know who A's patients were. Will you kindly advise me as to whether I can put a stop to this advertising or not, and if so what are the steps to be taken? Thanking you in anticipation, Yours truly,

April 28th, 1901. MULLACH ADOO

⁂ The only course is to give information to the General Medical Council and to be prepared to support the information. We do not approve of A's use of a door-plate upon a cottage which he does not occupy or use in his practice.—ED. L.

ANISOMETROPIA.

To the Editors of THE LANCET.

SIRS,—Would you kindly oblige me with the name and publisher of some book containing examples of prescriptions for anisometropia, &c., and similar defects of vision, by means of glasses? Do you know if Morton's book, "Refraction of the Eye: its Diagnosis and the Correction of its Errors," gives such? In standard works such as Fuchs's, Swanzy's &c, no examples of such troubles are given. An American book would suit. I am, Sirs, yours faithfully,

April 23rd, 1901. A. B. A.

⁂ The Refraction of the Eye, by Edward Davis, M.D.; Macmillan, 1903. James Thorington, M.D., Refraction and How to Refract Rebman, London, 1900. George F. Helm, M.D., Short Sight, Long Sight, and Astigmatism; Churchill, London, 1886. The successive numbers of the *Optician* (Giltenburg Press, London), published weekly for several years past, contain in answer to correspondents many very intelligently worked out replies to questions on refraction.—ED. L.

DOUBTFUL ADVERTISEMENT.

THE following advertisements appear in the *Boston Independent and Lincolnshire Advertiser* of Saturday last, April 27th:—

CHANGE OF ADDRESS.

DR. ——— has Removed from 118a, High-street, to
SOUTH-STREET, BOSTON.

MISS BELL, Experienced Laundress, has removed from No. 22, Liquorpond street, to 43, LIQUORPOND-STREET, Boston

We do not recommend our readers to imitate the examples set of advertising in the press their changes of address. Such advertisements by medical men occasionally come under our notice, and we do not doubt that in the majority of cases there is no intention of infringing medical etiquette; but they open the door to abuse, for no rule can be laid down to decide how long such advertisements should appear. The fact that a man has changed his address should be made known to his own patients and to nobody else outside the circle of his private friends and his tradesmen.

◆

A. B.—An agreement ought to have been made before the rather complex arrangement for working the practice was started. As B has now to pay for a share in a practice of which he has had the sole management for three years, we think that the price which he pays should be regulated to a certain extent by the influence that he has had upon the receipts. But if the value of the practice through his sole exertions has considerably appreciated during the three years it is hard that he should have to pay a considerably increased sum to enjoy further benefits. His partner, who for three years has been a sleeping partner, will in these circumstances derive benefit from B's unaided exertions, and should, we think, be ready to make lenient terms with B. Owing to the absence of an agreement the matter is one upon which no definite opinion can be given, but from our correspondent's account we feel that it would be best for the two partners to select an arbitrator trusted by both of them and to abide by his decision. It would be a pity if they did not start on their joint venture amicably.

Compensation.—"Where a workman has given notice of an accident he shall, if so required by the employer, submit himself for examination by a duly qualified medical practitioner *provided and paid by the employer*, and if he refuses to submit himself to such examination or in any way obstructs the same his right to compensation, and any proceeding under this Act in relation to compensation, shall be suspended until such examination takes place." It will be observed that the medical practitioner is to be "provided and paid" by the employer, but as there may be a dispute as to payment if such an examination is made without direct authority from the employer and before payment the medical man who makes an examination should see that there is no doubt that he is "provided" by the employer and that the employer understands his liability towards him.

Eclectic.—We have no information on the matter.

METEOROLOGICAL READINGS.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

During the week marked copies of the following newspapers have been received:—*Swindon Advertiser, Yarmouth Mercury, Keighley News, Scotsman, Leeds Mercury, Exeter Times, Grantham Journal, Times of India, Pioneer Mail, Architect, Citizen, Liverpool Daily Post, Sanitary Record, Fife News, Bristol Mercury, Huddersfield Examiner, Stamford Guardian, Yorkshire Post, Builder, Otago Daily Times, Sheffield Daily Telegraph, Dundee Advertiser, Birmingham Gazette, Cardiff Express, South Wales News, Glasgow Mail, Truth, Newcastle Leader, Bradford Argus, Carlisle Journal, Sussex News, Sunderland Echo, Northampton Reporter, Boston Independent, Reading Mercury, Australasian Medical Gazette, City Press, Hertfordshire Mercury, Local Government Chronicle, Islington Gazette, Christian Globe, Ceylon Standard, Sydney Mail, Commercial Intelligence, Mining Journal, Surrey Advertiser, Grimsby Daily Mail, Local Government Journal, Luton News, Consett Guardian, Yeovil Chronicle, Church Family Newspaper, Forfar Herald, Weekly Free Press and Aberdeen Journal, Blackpool Times, Tewkesbury Record, Invention, Westminster Budget, Literature, Thirsk News, Gloucester Chronicle, North Suffolk Advertiser, Stafford Advertiser, Cornish Guardian, &c., &c.*

Communications, Letters, &c., have been received from—

The Erasmus Wilson Lectures

ON

THE PATHOLOGY AND DISEASES OF THE THYROID GLAND.

Delivered at the Royal College of Surgeons of England on Feb 18th, 20th, and 22nd, 1901,

BY WALTER EDMUNDS, F R C S ENG,

SURGEON TO THE TOTTENHAM HOSPITAL; SURGEON TO OUT-PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN

LECTURE I

Delivered on Feb 18th.

MR PRESIDENT AND GENTLEMEN,—The subject of the lectures which the Council has done me the honour to elect me to give is the Pathology and Diseases of the Thyroid Gland The subject is not new to this theatre, for in 1891 Mr James Berry selected the pathology, diagnosis, and surgical treatment of goitre for the Hunterian lectures which he gave that year, but in the 10 years which have since elapsed considerable progress has been made in our knowledge of the physiology of the thyroid gland, and it is therefore convenient to reconsider our views as to the nature of its diseases, and more especially of Graves's disease, in the light of these advances

The thyroid gland consists mainly of closed vesicles lined with epithelial cells which secrete the colloid, it may here be remarked that the normal vesicles are in shape round or square (in some conditions they become branched and stellate), that the secreting cells are cubical (in some conditions they become columnar), and that the colloid readily stains with the usual microscopic agents (in some conditions it does not stain) It may be added that the nerves to the thyroid have been traced into close proximity to, but not actually into, the secreting cells Besides the thyroid proper there are certain small glands named "parathyroids" Recent researches have shown these to be of much importance in the organism, indeed, their excision generally causes the death of the animal These glands were no doubt observed from time to time by various anatomists, but the first full account of them was written by Sandström of Sweden in 1880 In this country they were independently described by Cresswell Baber in a paper published in the Philosophical Transactions of the Royal Society in 1881 The parathyroid glands differ from the thyroid gland proper in that they consist wholly of cells and contain no vesicles and no colloid, or at most a minute droplet (Fig 1 and Fig 2)

It is not easy to identify the parathyroid glands in the human subject because some of the minute outlying nodules are found to consist of ordinary thyroid tissue and to be therefore accessory thyroid glands, only those that consist exclusively or mainly of cells are to be regarded as parathyroid glands The anatomy of the parathyroid gland in man has been worked out by Dr D A Welsh of Edinburgh He finds that there are four of these glands—one anterior and inferior to one posterior and superior to, each thyroid lobe The parathyroid glands are said to differ from the thyroid gland proper in another way—developmentally, they develop in advance of the thyroid lobes

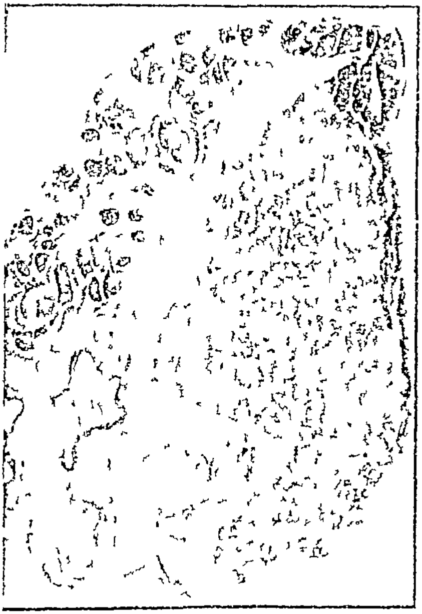
We can study the physiology of the thyroid gland by operations for its removal in whole in part, or in successive parts, also by the administration of preparations from the thyroid gland or from the parathyroid glands

The earliest experiments on excision of the thyroid gland were made by Sir Astley Cooper as long ago as 1824

In 1844 Sir John Simon made an important contribution to the subject He proceeded by the very Hunterian method of studying the comparative anatomy of the organ and embodied his results in a monograph on the thyroid gland in vertebrata which was published in the Philosophical Transactions He came to the conclusion that the thyroid gland is intimately concerned in the nutrition of the central nervous system and in the regulation of the circulation to the brain It is interesting to note that these views arrived at more than half a century ago mainly through comparative anatomy have recently received confirmation from the experimental methods of to-day

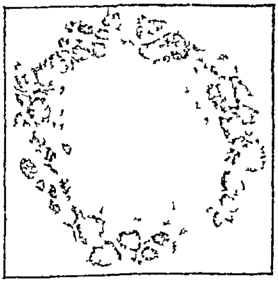
In 1856 and 1857 Schiff made a series of experiments He showed clearly the fatal results that usually follow the complete excision of the thyroid gland in dogs and cats But not much attention was paid to the subject till 1882 and 1883, when Reverdin and Kocher respectively reported cases of excision of the goitrous thyroid gland in the human subject which was followed by serious, and in some cases fatal, results Schiff now repeated his experiments and he has been followed by numerous observers The subject, however, has proved rather complicated, as the results apparently differed in different kinds of animals

FIG 1



Normal parathyroid gland of the dog A small part of the adjacent thyroid gland proper is shown and can be recognised by its vesicles containing colloid In the dog the parathyroid gland lies on the surface of the thyroid gland (× 60)

FIG 2



Normal parathyroid gland of the monkey The parathyroid gland is completely surrounded by the thyroid gland proper

Sir Astley Cooper's experiments were made on the dog, and it will be convenient in the first place to consider the now well-established results which follow the complete extirpation of the thyroid gland and the parathyroid glands in the dog. The symptoms commence generally about 48 hours after the operation. One of the first symptoms noticed, probably the first if the animal is closely observed, is a fibrillar twitching of the muscles; this can be seen, and it can also be distinctly felt by placing the hand on the dog. Within a day or two this is often followed by a severe attack of general convulsions; the animal lies down—in fact, it cannot stand—as its limbs are in a state of spastic paralysis; further, its respirations are hurried, rising to 200 a minute or more. Also during the attack its temperature is raised, sometimes as much as several degrees. These attacks last for an hour more or less and completely pass off, so that the next day the animal appears to be itself again. The convulsive attacks may recur and in a day or two other symptoms may appear; the dog becomes much less lively—in fact, quite listless. Its hair falls out and a peculiarity is noticed in its gait; also it has a difficulty in maintaining its equilibrium, especially when turning round. Later a rigidity is noticed in its limbs, and before long its hind legs may become completely paralysed; trophic symptoms may come on, such as ulcers on the skin, also a conjunctivitis followed by a keratitis leading to destruction of the eye. It may be added that the urine sometimes contains albumin and more rarely sugar; also that between the convulsive attacks the temperature is subnormal. Finally the animal dies on about the fifth day, but death may occur at any time between the second and the eleventh day, or even later.

There is one other point which, considering its bearing on Graves's disease, ought not to be overlooked, and that is whether there is any alteration in the prominence of the eyes. It is much affected; the palpebral fissures become narrower and the eyes less prominent.

The great majority of the dogs submitted to total thyroidectomy die, but a small percentage recover; this result seems to be common to nearly all observers, and cannot therefore be explained away by error of experiment. We must conclude that even in dogs and cats total excision of the thyroid gland and of the parathyroid glands is not necessarily a fatal procedure, while in other less extensive operations we must be prepared for an absence of absolutely conclusive results.

Now, although the operation was followed in dogs and cats with so great a mortality it was found to produce no effect whatever in rabbits. It was soon shown, however, by Gley that the contradiction was only apparent, for he found that two of the parathyroid glands in rabbits lie separate from the thyroid gland proper, and consequently escape removal when the thyroid gland is excised. Gley found that when these were also removed the rabbit, as a rule, died.

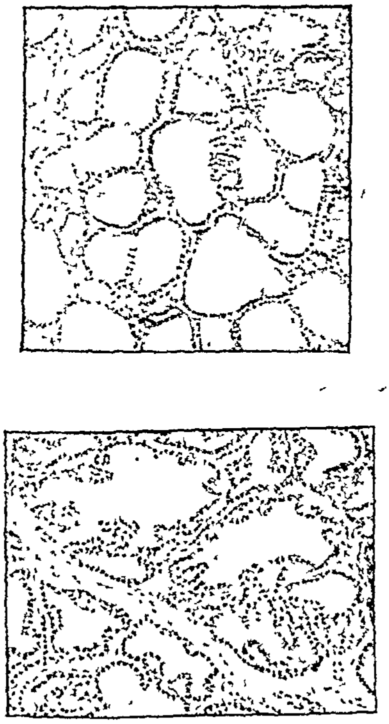
In monkeys total excision of the thyroid gland produces symptoms similar to those seen in dogs. The majority of monkeys thus operated on have tremors and convulsions and also passing paresis of the limbs. They have, too, œdema under the eyelids, and occasionally well-marked swellings there. Finally, the monkeys nearly always die, many with acute nerve symptoms similar to those seen in dogs; others have, as was first pointed out by Horsley, symptoms identical with myxœdema in man. The hair falls out and swelling occurs in the face which is especially marked under the eyelids. In monkeys, too, enophthalmos and narrowing of the palpebral fissures occur, but exceptionally widening of the palpebral fissures may be seen.

The fatal termination in dogs cannot, as a rule, be prevented by thyroid gland feeding or by the subcutaneous injection of thyroid extract. The conclusions which I arrived at from some experiments on this point were that the symptoms were somewhat modified, the attacks of convulsions with rapid breathing being less frequent; that death occurred on an average a few days later than in untreated cases; and that the small percentage of recoveries was somewhat increased. Cunningham came to similar conclusions: he found that by thyroid gland feeding the lives of thyroidless dogs could be prolonged from an average of from 52 to 54 hours to an average of from eight to 12 days. It has been thought that the lives of the animals might be saved by grafting into them the excised thyroid lobes, and with this view a lobe has been returned to the site from which it has just been excised or it has been placed in the abdomen. The result, however, in most cases at least, has been that the grafted lobe has simply been absorbed (that certainly has been the result in my experiments on this point) and the dog has died. This treatment, however, is not absolutely without effect, for during the process of absorption the lobe acts as thyroid gland food and the course of the ailment is slightly modified accordingly. In monkeys, too, thyroid gland feeding, although it modifies and prolongs the course of the disease, fails as a rule to save the life of the animal. Such, then, are the results of total excision.

If in a dog one lobe of the thyroid gland, together with its two parathyroid glands, is excised, leaving the opposite lobe with its two parathyroid glands, no obvious effect is produced on the dog; and if the remaining lobe and its parathyroid glands are subsequently removed the dog dies, and this occurs no matter what the interval between the two operations may have been; similarly with piecemeal excision, the dog dies after the removal of one of the later pieces.

Although no symptoms occur in a dog as a consequence of the removal of one lobe of the thyroid gland important changes occur in the lobe which is left; as was pointed out by Wagner, it hypertrophies. The microscopical changes were first described by Horsley; the vesicles enlarge and become branched, the cubical secreting cells become columnar, and the colloid disappears and is replaced by a mucous secretion which takes the staining reagents badly (Fig. 3, Fig. 4, Fig. 5, and Fig. 6).

FIG. 3 AND FIG. 4.

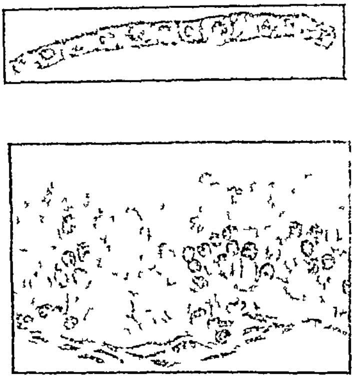


The upper figure shows the normal thyroid gland of the dog. The lower figure shows a portion of the thyroid gland left *in situ* for 41 days after the whole of one lobe and nearly the whole of the other lobe of the thyroid gland had been excised, leaving only one parathyroid gland and a small portion of thyroid gland proper. The vesicles are enlarged and their lining membrane is folded. The colloid has nearly disappeared. The drawings are to the same scale. (× 90.)

Whether there is any difference in the physiological action of normal colloid and that of the secretion in compensating hypertrophy we do not yet know, but it is a point worth investigating. In order to ascertain to what extent the symptoms produced by total excision are due to the excision of the thyroid gland proper and to what extent to excision of the parathyroid glands it is necessary to excise them separately. In dogs if one parathyroid gland be dissected free from the thyroid lobe, taking care not to interfere with its blood-supply, and be left in the animal, and the rest of the thyroid gland on that side be excised and also the whole of the thyroid gland with its two parathyroid glands on the opposite side, so that only one parathyroid gland be left in the animal, the dog will live and no obvious effects will ensue; such, at least, is the usual result. If the parathyroid gland is subsequently excised the dog will die with the usual acute symptoms The parathyroid glands that are left in these experiments show signs of more active growth than the normal, but they do not develop into thyroid tissue proper No vesicles form This it will be noticed, tells against the view that was once held, that the parathyroid glands are undeveloped thyroid tissue

In rabbits the excision of the thyroid lobes with the two attached parathyroid glands, leaving *in situ* the two other parathyroid glands, produces, as already stated, no immediate effect, but if the animals are kept for several months the following symptoms may arise In four experiments I noticed (1) failure of health, (2) hair falling out, and (3) a swelling of the lower part of the face, presumably myxœdematous in nature Dr G R Murray of Newcastle has also observed myxœdematous changes coming on late in rabbits which have been deprived of their thyroid glands proper With respect to the condition of the eyes in these animals which have been deprived of their thyroid glands proper, in dogs I have not noticed, as a rule, any change, but in one dog still under observation there have recently come on symptoms—tremors and spastic gait—and for months past it has been noticed that the eyes have appeared sunken and the palpebral fissures narrower, these symptoms are getting worse In rabbits a series of experiments were made especially to test this point, the result was that there was found a marked tendency for the eyes to become narrow, if eventually the animals died from thyroid symptoms the eyes became very narrow

FIG 5 AND FIG 6.



The upper figure shows the normal secreting cells lining the vesicles of a dog's thyroid gland The lower drawing shows the same cells from a small portion of the thyroid gland which had been left together with a parathyroid gland 132 days after the greater portion of the thyroid gland had been excised The drawings are to the same scale (× 600)

MEMORIAL HOSPITAL COT—Dr W F. Clarke, as trustee of the estate of the late Mr James Ewen Maddilove, has forwarded to the treasurer of the City Orthopædic Hospital, Hatton garden, London, £1000 to endow a cot in memory of Mr Maddilove's daughter

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN – On May 1st, in fulfilment of a promise given some few months ago to the Duchess of Beaufort, Earl Roberts visited Bristol for the purpose of opening a bazaar held in Colston Hall on behalf of the funds of the Royal Hospital for Sick Children and Women Earl Roberts, who was received with great enthusiasm, in the course of his speech alluded to the fact that for some years past the annual expenses of the hospital had exceeded the income by £1300, and that at the present time there remained a deficit balance of £3000 The bazaar, which lasted for four days, was most successful, and it is thought that a substantial sum has been raised for the hospital

---

An Address

ON

THE IMPORTANCE OF THE TEACHING OF INSANITY TO THE MEDICAL STUDENT AND PRACTITIONER IN RELATION TO THE PREVENTION OF INSANITY.

Delivered before the South Eastern Division of the Medico-Psychological Association on April 24th, 1901,

BY ROBERT JONES, M D M R C.P. LOND,
RESIDENT PHYSICIAN AND SUPERINTENDENT, LONDON COUNTY ASYLUM, CLAYBURY

GENTLEMEN,—I venture to take for my subject the teaching of insanity in a somewhat wider sense than that for the medical student only; in part because of the increased public interest which the subject has caused through enormous expenditure necessitated in housing and accommodating the victims of this disease, in part, also, from the loss to the community through the permanent disablement and consequent unproductiveness of those who fail to recover from it Acres of print are blown on to us daily from the four winds, and some apology may be needed for pinioning these thoughts in manuscript and placing them before you Mine shall be this—that as we are all members of a great association to which this subject in all its bearings is and ever must be a matter of the very greatest concern I may be permitted to claim your attention upon an aspect which may tend very materially to modify its extension Such, I take it, is the aspiration of our hearts and the exertion of our hands

This association, which was established in 1841, can look back upon 60 years' record of lively and unbroken interest in the welfare of the insane It has ever assisted efforts made for the amelioration of those suffering from this most melancholy and grievous of human afflictions Its prosperity is in no small measure due to the manner in which its council has adhered to the objects for which the association was established—viz, "the promotion and cultivation of science in relation to mental disorder, the improvement of the treatment of the insane and the maintenance of the honour and interests of the medical profession generally" How the "medical profession generally" is to become conversant with this particular branch of medicine is the subject of this paper All of us are agreed that the commencement must be in the proper training of the medical student and many of us recall the difficulties which accompanied our own early efforts in the proper comprehension of this subject

Within a few years of the foundation of the association a general revival grew up in matters medical In 1855 an arts examination became necessary as a preliminary to a medical career, for which credit is due to the Society of Apothecaries In 1858 the Medical Act was passed creating a system of registration and bringing into existence the General Medical Council Since this year—recognising that the fundamental pathological conception of disease is biological—an infinite addition of subjects favouring in the main the appreciation of natural science has been made to the students' curriculum, and this has greatly influenced not only the intellectual status but also the social standing of the profession It was not until 1893, however, that the General Medical Council made it compulsory for the student to attend a special course of instruction in mental diseases Some of our teachers in the medical schools still consider a proper study of this subject to be subsidiary and only likely to distract the student from what they believe to be more urgent and more important departments I shall endeavour to give reasons why the study of mental diseases is in itself important by pointing out the bearing upon, and the utility of, this subject to the varied duties of a medical practitioner, and finally to suggest methods for its fuller and more complete apprehension

To day there are no less than 30,000 medical men (and women) in Great Britain and Ireland out of a population of over 40,000,000 Of this total there are nearly 145,000 persons (in England 108,000, in Scotland 16,000, and in Ireland 21,000) who are insane under more than 150,000 certificates, giving an average of one insane person to every 266 (or at the outside to every 300) persons of the population, or five certificates to every member of our profession. It is, moreover, asserted that for every certified insane person there is probably another who is either suffering from a threatened attack or who may be harmless and yet insane, and as to whose security and safety, either in his own home or in a special hospital, his medical attendant is expected to give the best advice.

The certificate referred to contains two propositions—one that the individual is of unsound mind, the other that he is unfit to be trusted with his liberty. Of these the second has a practical importance which it is difficult to over-estimate, for it not only dispossesses the individual of his liberty, but it also disfranchises him, deprives him of the control of his own affairs, alters his position to his friends and his responsibility to the law, and of necessity by disturbing his social relations causes the greatest distress to his relatives. In addition to this it causes in the present state of public opinion a stigma to attach to himself and all his connexions. He is practically incarcerated until he himself shows that he is entitled to his restoration. It is not surprising, therefore, that the law imposes upon the medical man a certain responsibility for this duty by enacting that "any person who makes a wilful mis-statement of any material fact in any medical or other certificate or in any statement or report of bodily or mental condition under this Act shall be guilty of a misdemeanour." As to the statements in certificates, it has been pointed out that there are singularities and eccentricities which do not constitute the minor degrees of insanity, and it has been asked if suspicions and conspiracies are in their nature necessarily insane? May not suspicions be reasonable or just? Is the world so pure and honest that persons never conspire against the prosperity of individuals? Can antipathy for those who were formerly loved be sufficient ground for incarceration? Are the acquaintanceships and friendships of sane men like the laws of the Medes and Persians? Are there no natural and reasonable changes from kindly feelings to animosity depending upon the sensibility of the individual? Where is the line between that excess which is, and that which is not, decisive of insanity? Are the facts assigned the result, as they should be, of a careful examination and a direct inquiry into the person's present conduct as compared with, and illustrated by, his demeanour and conduct through his previous life, or are they merely inferences? Realising this importance the law requires that one of the certificates shall, whenever practicable, be under the hand of the patient's usual medical attendant who is supposed to be conversant with his ethical standard and would be sooner able to notice and apprehend any change in his mental reaction, and the reasons for changes in his conduct. Failing this the petitioner (53 Vict., cap. 5, sec. 31) has to state the reason for the omission or the certificate is invalid.[*] It should never be *inferred* as a necessary consequence to singularity of mood and manner, or to delusions and unsoundness of mind, that the individual is a "proper person to be taken charge of and detained under care and treatment," but it should, as stated, be made the subject of direct inquiry and investigation. We are not concerned here as to what constitutes insanity, but Dr. Johnson probably lighted on the truth when he said that "madness frequently discovers itself merely by unnecessary deviation from the usual modes of the world."

Nor is certification the only or the greatest responsibility of the medical man, for as the confidential family adviser his opinion is sought for as to professions and careers. He is eagerly consulted by anxious parents as to the development or retardation of certain faculties in childhood and youth—their application and relation to certain modes of study, education, training, and business. He is expected to use his knowledge to interpret the origin and growth of these faculties under varying hygienic conditions, so that influences which may be hurtful shall be avoided and the organism—that organic whole—shall grow up into healthy maturity. He has placed before him the mental hygiene not only of individuals but also of families and their relation to society. It is his duty to see that the health of the community does not fall below the standard of efficiency, as is the inevitable tendency in the inhabitants of large cities where overcrowding fosters and favours the three great determinants of insanity—viz., syphilis, drink, and unsuitable marriages—and where also a vicious circle of other social evils is established which eventually requires the strong hand of the earnest reformer to eradicate. It is also his duty to educate the rank and file of the population by inspiring them with a sense of their corporate responsibility in regard to the baneful influence of these evils upon the health and well-being of the community. Knowing that preventive medicine has long since passed from empirical rules to an art based upon physiological discoveries, he has to bring an educated medical knowledge to bear upon the customs of our civilisation, so that brains which had a tendency to disease by inheritance should not be subjected to undue pressure—realising the fell effects of "stress" upon the hyper-sensitiveness of a highly organised brain whose cells have been rendered unstable through the selective action on them of a special toxin, and recognising at all times the true and full significance of the first signs of danger, so that the further onset and progress of disease might be arrested, and mental and physical surroundings be secured consistent with evolution along normal lines. He should thus be a student of social conditions, able to interpret, to clarify, and to utilise by whatever method science can adopt the multifarious and perplexing experiences presented to an intelligent mind, so as to assist in working out the problems of nature for the higher evolution of man, bearing in mind that progress consists in the advancement of humanity from the less to the more perfect—from homogeneity to heterogeneity—causing "manners to be milder, habits to be more social, institutions more just and liberal, knowledge more diffused, beliefs more reasonable, and life easier." The medical adviser is consulted, again, as to engagements and marriage, and that this is a serious question may be gathered from the fact that the insanity of nearly 10 per cent. of all women admitted into asylums up to the age of 45 years is referable either to pregnancy, delivery, or lactation. The destiny of the race does not enter into the consideration of matrimonial alliances as it should, and the education of women in the present day—upon whom the happiness of the home depends—tends to emphasise the pleasures of life rather than the happiness of duty. It is the work of the medical adviser to alter this and he should be a man of parts, accustomed to actual contact with men and matters, and to the comprehension of what things *mean*, how they *consist*, and why one event follows another. He should be able to give an opinion based upon an acquaintance with that biological law according to which all beings endowed with life tend to repeat the elements and functions of their organism in their descendants—a law which governs the subordinate no less than the dominant characteristics, and which involves internal and external structures with their physiological and psychological consequences. Again, the medical adviser may be consulted as to civil and testamentary capacity, and he may be called upon to decide questions of criminal responsibility. Crime is in many cases traceable to degeneration and to physical conditions similar to those associated with insanity, and these may co-exist or be combined in an infinite variety of proportions. In the study of mental pathology various physical abnormalities are frequently found, and although the measurements of individuals may give rise to great variations in every race there are some tangible differences by which the broader divisions can be distinguished, and we can find, at all events, that certain characteristics prevail in one and certain others in a different race. Anthropology will prove of value in determining the nature and amount of the resemblances and differences in the physical characters of the various groups into which the human species is divided, thereby throwing light upon their history and their origin and the relation they bear to one another. Such measurements as the cranial capacity, the cephalic (latitudinal or breadth) index—as giving the dolicho-, mesati-, and brachycephalic skulls; the altitudinal, alveolar, nasal, and orbital indices—all these furnish the basis of classification in craniometry, and should be familiar to the advanced student. As to responsibility, on the other hand, it incurs liability to authority and legal punishment, and before the question of criminal responsibility is decided the origin of moral distinctions, the freedom of the will, and the nature of conscience present themselves for consideration and discussion, for which an acquaintance with the disciplinary sciences, psychology, ethics, logic, and metaphysics, may prove at least serviceable if not necessary.

The medical adviser is also confronted with grave mental symptoms arising in the course of bodily diseases and these may require home treatment without the option of special hospital assistance. Obviously, therefore, there exists a considerable amount of brain disease involving abnormal mental conditions with which it is obligatory upon the medical practitioner to be conversant in all its phases This, confessedly the most difficult branch of medicine, must be approached in precisely the same manner as any other—physiology must precede pathology, experiment and induction must verify hypothesis The normal mind must be observed and studied before the abnormal can be understood, and the study is one which tends to develop the reflective and perceptive habits and helps to make the student quick to apprehend reasons for changes of conduct and so to bring himself into more complete harmony with his patient

Furthermore, one of the chief reasons why the medical student should be familiar with this study is that insanity is best and most successfully treated in its early stages, and its recognition in this stage becomes, therefore, most important The disease is more likely to be fatal in direct proportion to the delay which has taken place before commencing treatment—in other words, the earlier that cases of mental disorder come under treatment the higher is the percentage of recovery, and the chances of recovery diminish considerably and progressively as the time before commencing treatment increases in duration. The successful treatment of insanity means attacking the disease in its incipient stages—the stages of abstraction, reverie, pupillary changes, insomnia, and capricious appetite By observing these, calamities may often be averted, grave scandal prevented, and the innocent saved from ruin I have referred to the ban of society upon insanity Similarly in remote times was the view held as to surgery and obstetric medicine, but we can scarcely hope to remove this so entirely as has been done in other departments Insanity in ancient days was viewed as a disease of our moral constitution, based doubtless upon the fact that the disease may—as in the case of "stress"—be due to psychic causes The mind does very directly affect the body The perusal of a letter or the sudden communication of bad news may strike the stoutest to the ground and render the broken heart something more than a metaphor Fear can paralyse the limbs, hope can instantaneously give soundness and vigour to the frame as much as despair can render it lean and tottering A word, the sight of a person, will crimson the cheek In the presence of a materialistic philosophy we are in some fear of disregarding this aspect of causation. Aided by discoveries in physical and chemical methods, by the great progress of physiology and histology, we tend to believe, through accurate observation and accurate recording, that insanity is exclusively a bodily disease Gross mental decadence is certainly associated with great neuronal changes In dementia very obvious atrophic changes in the nerve-cell and marked destruction of nerve fibre plexuses are found Analogy, therefore, supports the belief that the so-called functional and hysterical conditions may be correlated with slight neuronal changes, and it is within the limits of possibility that these may be initiated by mental causes On the other hand, the organism is not an individual but a "social mechanism," it is a collective being and each of its single parts must be understood as a factor of existence The life of an organism is the sum of the lives of the single cells, and it is only intelligible by the life of each part Cells are composed of granules of organic chemical substances which are not themselves alive but the mechanical arrangement of which determines the direction and arrangement of their activity These granules, which form the working units of the cells, are—viewed from the materialistic side—probably storehouses of energy, the breaking up of which is accompanied by a liberation of energy as possibly manifested in delirium Indeed, it has been observed and recorded that nuclear degeneration within the nerve-cell is peculiarly associated with certain states of motorial and mental instability.

As to the *materies morbi* in mental diseases we are probably upon the threshold of important discoveries Physiological chemistry reveals substances in the animal body which are capable of affecting unfavourably the somatic and neural cells, and we are able to separate the effects of these toxic agents according as to whether or not the symptoms which accompany the morphological changes induced in these cells are specific and tangible, and therefore pathogenic As to this great question of toxicity we know that all living organisms both in health and disease are manufacturing toxins—"toxicity" being a term which has come to signify the various alterations of nutrition from the normal standard—and we know also that these may be neutralised by antitoxins which, whether they are toxoid or of the nature of a proteid molecule, enable the organism by means of these immunising substances to resist the invasion and to stop the growth of a deleterious disease otherwise fatal to it, possibly by the linking-on of toxin to proteid bodies and the formation of "anti-bodies" The toxins generated within the system by excessive production or imperfect excretion give rise to symptoms of auto-intoxication which can in many bodily diseases, such as gout, rheumatism, dropsy, influenza, pneumonia, and typhoid fever, be separately identified Possibly toxins due to altered or varying assimilation may be at the root of the different temperaments and the elements of personality may be thus explained. "The fathers of medicine" may have been more correct as to the explanation of diathesis by humoral variations than it is our wont to believe We now know that the brain, like other tissues and organs, is composed of cells and their derivatives, and it probably reacts similarly to the influence of organisms and agencies, but it is only by minute microscopic and chemical investigation that the essential nature of disease, whether of the brain or other organs, can be ascertained. The grey mantle of the cerebral cortex has long been recognised as the sole organ of mind, affecting and dominating all the tissues of the body, controlling their functions and regulating their energies It occupies the "supreme rôle" in the nervous hierarchy. It is here that the "tissue of the mind" lies and it is here, also, that the activities work which underlie conscious states This grey envelope merits study, for it receives the terminal extensions of all in-going channels from the outer world and forms the origin of all out going currents to the outer world.

I have now shown how important is the study of brain functions and mental disorders and how this is a subject which concerns the jurist, the sociologist, the biologist, the priest, and the politician I have referred to and enumerated the various ancillary sciences which assist its complete apprehension As, however, for the student the number of subjects is extensive and the number of facts to be acquired appalling and as he is already almost overpowered by his load, we must be content with less of the disciplinary requirements than should otherwise be exacted and insist somewhat upon the simplification of learning, urging only those portions which are eminently practical, remedial, and to the point, so that the mind should be trained in accurate and methodical observation to seek for truth in her many masqueradings. The student should be fully conversant with neurological methods and have a technical knowledge of those made especially clear to him in the histological course. Further in the separate course upon pathology he should be trained in the preparation of specimens and the methods of staining morbid tissues more especially in relation to changes in the normal secretions—what may be called clinical microscopy. He should receive a more practical instruction in the use of physiological instruments and be accustomed to the ordinary manipulation methods of blood examination, pressure instruments, and chemical analyses His medical training should include especially ophthalmology and the application of medical electricity. As complete a knowledge of psychology or mental physiology as the present state of the science admits is strongly urged by means of a systematic course of instruction upon the normal processes of the mind. The senses being the ordinary avenues of experience must be understood and their action and reaction explained by the modern methods of psycho-physics with especial reference to the laws of stimulation Terms should be explained and defined and such mental activities as apperception, memory, belief, attention, reasoning, will, judgment, and imagination fully entered into, so that their abnormalities—illusions, hallucinations, delusions, obsessions systematised beliefs, and other anomalies of the will—may be more fully appreciated Owing to the metaphysical aspect of ethics this branch may be left to the more advanced student The great end in view being the early recognition and the practical treatment of cases which students are likely to meet with in general practice, great stress should be laid upon clinical instruction The different forms of insanity should be described in a systematic course of lectures and each such lecture should be alternated by describing and showing typical cases in the hospital or the asylum. The student should be encouraged to come into actual contact with cases by signing certificates of cases already under treatment, such as those who would come up for re-certification, and he should also be brought in to watch the treatment—medical and moral—of actual cases. He should be present at the post-mortem examinations and have typical pathological demonstrations made to him. The whole of the course should be interrupted by occasional oral and written examinations personally and in class.

I would further suggest that the conjoint colleges and the new London University—following in the line of our own association—should inaugurate a diploma in mental diseases similar in scope to that in public health and that all medical officers of asylums and hospitals for the insane, and those attached to licensed houses, should be encouraged to take it, until eventually it would become a recognised and necessary qualification to hold office—as is the diploma referred to for medical officers of health. The fact that at the present time there are about 1000 appointments in this branch of medicine in the United Kingdom, from that of Lunacy Commissioner downwards, should imply an honourable obligation that the holders of these offices should themselves be equipped with as full a knowledge of this subject as can be comprised in the general technique of neurological methods, psycho-physics, and the special philosophical disciplines of logic, psychology, and ethics, together with a complete systematic and clinical knowledge of insanity and the enactments bearing upon it.

One word as to the unifying of knowledge which is presented to our experience. The philosophical thinker who reflects upon the meaning of life—and we all do so in our different ways—attempts to arrive at his conclusions in a reasoned and comprehensive way. He attempts to get at the vital and essential meaning of the world in its entirety and not exclusively in reference to the laws of a certain group of facts He dwells (1) upon the importance of conduct; (2) upon the nature of the external world; and (3) upon the existence of super-sensitive realities. Far be it from me to suggest that the expert in mental diseases should attach undue importance to the abstract aspect of this subject, but I think that if the actual values of our experiences could be harmonised and united certain questions must of necessity present themselves, such as the origin of knowledge, the basal reality which gives us the unity between mind and matter, and the purposive or mechanical relationship which these bear to the laws which govern the material world. Such considerations may help to give us the unity we seek and present to us a more simple system by which life as a whole and the conception of things can be appreciated.

Finally, as to the further prevention of insanity, I would venture to hope that every public asylum in the country should become a school for a post-graduate course of teaching, affiliated if possible to a general hospital, where not only the undergraduate could receive practical instruction by offering them clinical clerkships and other posts, but also where any qualified medical practitioner could refresh his knowledge of the subject in all its bearings through one or other of the medical officers and to whom by means of an introduction from the local medical practitioner, or a member of the visiting committee, any applicant suffering from premonitory symptoms of incipient insanity could apply for advice. This, or a modification thereof, has been inaugurated for some years at the West Riding Asylum, Wakefield, and recently at the Dorchester Asylum, and in certain general hospitals, more particularly in London, the experiment has proved eminently satisfactory. The London County Council and other public authorities have now the opportunity of supplementing university training and rivalling the enterprising action of the Edinburgh Corporation who, by their enlightened and beneficent scheme inaugurated in the past the great extra-mural school of medicine which has now become the school of the Royal Colleges of Physicians and Surgeons. Their action would tend to improve the teaching of this subject, which beyond all others inspires terror and causes a sense of helplessness; it would also tend to the stimulation and endowment of chairs in the new University of London, and thus promote the public weal by encouraging the rich to contribute to their own freedom from disease, as well as assist those who could not avail themselves of the best advice. As the aim of our profession, which can claim to be altruistic above all others, is to render growth more perfect, decay less rapid, life more vigorous, and death more remote, he who, with hope as his watchword, succeeds, to whatever degree, in modifying this dreaded affliction, will not only have added to the alleviation of human suffering, but also have conferred material benefit upon those who are to come. He will have raised a monument to his fame far more durable than one of brass or marble, whose tablet shall be the heart of man and the letters thereon engraven by the tears of gratitude.

LOCAL v. GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY.

By THOMAS H. MORSE, F.R.C.S. Eng.,
CONSULTING SURGEON, CROMER HOSPITAL, AND VICTORIA COTTAGE HOSPITAL, WATTON.

THE subject of shock after operations and how to prevent it has often engaged my attention and I have wondered how much of the shock should be attributed to the operation itself and how much to the anæsthetic. Shock varies in proportion to the skill of the administrator and is often dependent upon the duration of the operation, and hence upon the amount of the anæsthetic which is inhaled. I have also observed that when abdominal sections have been performed with local anæsthetics little or no shock has followed. The causes of shock are especially twofold—viz., the anæsthetic and the extent of injury to nerve-structures produced by the operation.

I wish to consider this subject for the following reason. There are some patients whose condition of extreme exhaustion is such that the additional shock of general anæsthesia will just take away their only chance of life. Most of these are refused operation. The cases which I refer to are those of acute peritonitis, internal hæmorrhage, and intestinal obstruction. In the last class there is an additional special danger in all cases of stercoraceous vomiting; when ether or chloroform are given it is very likely that while the patient is unconscious some of the fæcal matter will be regurgitated from the stomach and sucked into the air-passages Now all of these are cases for operation with a local anæsthetic They are all desperate cases in which the patients if left to themselves will nearly all die, but many can be saved by a dexterous operation if performed without general anæsthesia I cannot better illustrate this subject than by quoting a few cases.

CASE 1. *Puerperal peritonitis.*—A primipara, aged 19 years, whom I saw with Mr. E. W. Everett on the fifth day after labour, was suffering from acute peritonitis. The abdomen was generally distended so that respiration was rapid and impeded, vomiting was frequent, and the pulse was extremely feeble (about 160 per minute) and only to be counted with difficulty. All the other distressing symptoms which usually accompany this condition were also present. Evidently neither ether nor chloroform could be borne. Mr. Everett injected six grains of eucaine under the skin in the middle line between the umbilicus and the pubes, and after waiting a few minutes I made an incision in the same place. No pain was caused by this. As rapidly as possible a large quantity of thin purulent fluid was washed out of the abdomen. No shock followed; in fact, the pulse was much improved, all the symptoms were relieved, and during the next few days her condition changed from one of impending death to one of apparent convalescence. I regret, however, to say that she did not recover, but died from sepsis somewhat suddenly at the end of a week.

CASE 2. *Ruptured tubal pregnancy.*—A woman, aged 27 years, whom I saw with Mr. T. A. Alexander at Watton, had been married for seven weeks and had menstruated only a fortnight before. She was suddenly seized with violent abdominal pain, followed by all the signs of internal hæmorrhage. There was extreme pallor of the face, the gums, and the lips, and the pulse could only imperfectly be felt, and could not be counted for 15 hours preceding the operation. The patient was most profoundly collapsed Mr. Alexander at once saw the necessity for operation, but at the same time he considered that no anæsthetic could safely be given. Accordingly it was decided to open the abdomen under a local anæsthetic. Water was freely administered by the mouth and per rectum.

Mr. Alexander used anestile to freeze the skin in the middle line below the umbilicus, and I then made an incision about three [illegible] the same time asking the patient if she [illegible] replied that she did not; neither was [illegible] cutting through the remainder of the abdominal wall. I found that the hand could be gently introduced into the abdomen without pain for the purpose of removing blood-clots, of which the whole cavity was full. The only painful part of the proceeding was that of dragging on the broad ligament for the purpose of pulling the ovary and tube up into the wound in order to ligature and remove them. The tube contained a pregnancy close to its uterine end not larger than a hazel-nut which was probably of less than a fortnight's duration. The abdomen was washed out as quickly as possible, several pints of warm water being purposely left inside, and the wound was closed without drainage. The pulse began to improve and could be counted directly after operation (160 per minute). No shock was caused and no part of the whole proceeding appeared to be very painful. In a few days the pulse had regained its volume and the patient, after much care from Mr. Alexander, completely recovered.

CASE 3. *Ruptured tubal pregnancy.*—A woman, aged 27 years, whom I saw with Dr. C. B. T. Musgrave and Mr. H. C. Dent at Cromer, arrived at that town by an excursion train from London in a very exhausted condition with all the signs of internal hæmorrhage. She was blanched and almost pulseless, and, in fact, in such a feeble state that no general anæsthetic could be given. The diagnosis of ruptured tubal pregnancy was made and it was decided to perform abdominal section. Mr. Dent froze the skin between the umbilicus and the pubes with anestile, Dr. Musgrave assisting. An incision was made three inches long without causing the patient to show any sign of pain; immediately the peritoneum was opened black blood escaped in considerable quantity. The right broad ligament contained a mass of about the size of a bantam's egg attached by recent adhesions to the surrounding structures. I found that pain was caused by dragging upon the broad ligament, but not by ligaturing it—in fact, I found that the patient complained more of pain from the heat of the water (110° F.) than from all the rest of the manipulations. Having removed the pregnant tube and the ovary the blood was washed out with a large quantity of hot water, several pints of the latter being purposely left in the abdomen, and the wound was closed without drainage. The patient's recovery was complete and was chiefly due to the unremitting care and attention that she received in the Cromer Hospital.

CASE 4. *Intestinal obstruction.*—A man, aged 61 years, whom I saw with Dr. F. L Pochin at Fakenham, upon whom it was decided to perform inguinal colotomy, was refused a general anæsthetic because, although the pulse was a fair one, he had stercoraceous vomiting. Eucaine was injected and after a few minutes the skin was frozen with ether spray. I then made an incision three inches long, very little pain being experienced while this was being done, and although the muscles twitched more than is usual with a general anæsthetic the man made no complaint on their being cut. The introduction of Paul's tube into the bowel was also painless. The operation was followed by no shock and the small amount of pain which was caused was easily borne, but the relief given was only temporary and the patient died about a week later.

CASE 5. *Strangulated hernia.*—A woman, aged 67 years, whom I saw with Mr. G. E. Deacon of Hethersett, was suffering from strangulated femoral hernia of 34 hours' duration. General anæsthesia was decided against on account of the vomiting and because there was a double aortic murmur. The skin over the hernia was frozen with ethyl chloride and the operation was accomplished with very little pain. There was no shock and recovery was uninterrupted.

As a contrast to the above cases I relate another case of intestinal obstruction which well illustrates the danger which I have alluded to when the stomach contains fæcal matter, as it did at the time of operation.

CASE 6.—A woman, aged 42 years, who was the subject of umbilical hernia, had had signs of incomplete obstruction lasting for nearly a week, the neighbourhood of the umbilicus being the chief seat of pain. The diagnosis was made that there was some adhesion causing partial obstruction connected with the old hernia. Ether was administered, the abdomen was opened, and a band was found adherent to the intestine and to the abdominal wall in such a way as to cause contraction of the calibre of the bowel. The band was divided and the obstruction was relieved, but while the abdominal wound was being sutured regurgitation of fæcal matter took place from the stomach and a small quantity of it was sucked into the air-passages. The patient immediately became cyanosed, and although she soon after regained consciousness and could speak yet she was unable completely to expectorate the fæcal matter and she remained in the same condition, breathing with difficulty, for four hours, when she died. This operation was quite a short one and would not have been painful if performed with a local anæsthetic.

I hope by the above cases to draw attention to the fact that life can be saved by operation even in desperate cases if general anæsthesia is avoided; it is also probable that pain is less acutely felt when the patient is *in extremis.*

Norwich.

THE ETIOLOGY AND TREATMENT OF CONVERGENT SQUINT[1]

By CLAUD WORTH, F R C.S. Eng.,
OPHTHALMIC SURGEON TO THE WEST HAM HOSPITAL; ASSISTANT, ROYAL LONDON OPHTHALMIC HOSPITAL.

I HAVE not been able to go through all my squint case-books in time for this paper, but my conclusions are drawn from the notes of 1278 of these cases. I shall endeavour to confine myself to facts based upon the experience of these cases and to avoid anything of the nature of theory or opinion.

The indifference often shown by laymen about squint in their children is very remarkable, yet when these children grow up, often with a hideous deformity only partially hidden by spectacles and usually with more or less blindness of the deviating eye, the patients or their parents would do almost anything if a cure could then be effected. There are few things more distressing than to have case after case presented for the first time only when irretrievable damage has been done by delay. There are two popular ideas to which this delay is often due. First, it is thought that the child may "grow out of the squint." In some rare cases the deformity does disappear spontaneously, but even in these cases the sight of the deviating eye is often much impaired, and binocular vision is very imperfectly acquired, if at all. Secondly, it is thought that if the child is treated for squint he will have to wear glasses always. The exact opposite is the case. A very large proportion of squinters, *if brought early* and treated in the manner which I am about to describe, will, before the age of puberty, be able to lay aside their glasses entirely, or perhaps to use them only for close work. Whereas, if no attempt be made to train the fusion faculty until the child is, perhaps, six years old, binocular vision, even if it be subsequently acquired, will be of such a feeble kind that it will never be able to withstand the strain of uncorrected hypermetropia.

The limited time at my disposal forbids my giving reasons for everything that I may say, so that, if my remarks seem dogmatic and contrary to generally accepted views, I hope that you will believe that I make no statement which I have not thoroughly investigated and proved for myself.

BINOCULAR VISION.

The fields of vision of the two eyes overlap everywhere except for about 40 degrees on the temporal side of each eye. When a distant object engages our attention the two eyes are brought into such a position that a picture of the object is formed simultaneously on the central part of each retina. Similarly all other distant objects, within the limits of overlapping of the visual fields, are focussed on *functionally* (not necessarily mathematically) corresponding points of each retina. The impressions thus received from the two eyes are blended in the brain so that we are conscious only of one single picture. This psychical blending of the two sets of impressions is called "binocular vision."

The fusion faculty is the potential faculty of binocular vision. For instance, a patient who has a convergent squint of 30 or 40 degrees may, during the continuance of the squint, have his fusion faculty trained and developed by means of the amblyoscope. This squinting patient ordinarily, of course, has not actual binocular vision, only a trained fusion faculty. But, while this patient is looking into the amblyoscope, and also after the cure of the deviation, the fusion faculty finds its expression in the act of binocular vision. In many cases a trained fusion faculty is in itself sufficient to cure the deviation. The fusion faculty is the key to the whole subject of the etiology and rational treatment of convergent squint. A patient may be highly hypermetropic and astigmatic and congenitally amblyopic, but if the fusion faculty is well developed it is extremely unlikely that he will ever squint. Conversely, in the case of a child who already squints, if the fusion faculty be trained *early*, in the manner which I am about to describe, the tendency of the case thenceforth is strongly towards cure. But to get this potent quality of binocular vision orthoptic training must be carried out early, not much later than five years of age, at a time when the development of the fusion faculty should normally be taking place. In investigations which I made with lights, prisms, &c., on healthy children in two large crèches I found the first distinct evidence of binocular vision at the age of six or seven months. The results of orthoptic treatment in young squinters seem to show that the fusion faculty normally reaches its full development by the end of the sixth year.

---

[1] A paper read before the Hunterian Society on April 24th, 1901.

CONVERGENT SQUINT.

In most of the text-books squint is defined somewhat as follows: "Squint consists in a deviation of the visual axis of one of the eyes from the correct position of fixation" (Fuchs). The authors have mistaken a single symptom for the whole disease. One might as well describe spinal caries as "a deviation of the spine from its normal shape." In a case of squint there is, in addition to (1) the deformity, (2) a defective development of the fusion faculty, (3) nearly always a suppression of the vision of the deviating eye, (4) in the great majority of cases more or less amblyopia of the deviating eye, and (5) refractive error. A mere remedying of the deformity of squint cannot therefore be claimed as a cure. We should aim at establishing binocular vision.

Even a monolateral squint is really a binocular affection. For instance, when we say that a certain patient squints with the right eye, what we really mean is that there is an abnormal convergence of both visual axes, but that the left being the better eye this eye is required to look straight ahead. In order to effect this both eyes make a conjugate movement to the left, so that while the left eye looks straight ahead the deviation of the right eye is doubled.

It is especially important to remember that squint is not a muscular affection. I find the power of independent outward rotation of each eye separately quite normal in 83·2 per cent. of my cases. In 9 per cent. there was some defect of abduction of each eye, and in only 7·7 per cent. was there any defect of outward movement confined to the deviating eye.

The deviation of a constant squint consists in an abnormality of the converging mechanism, whereby the zero of convergence becomes some cross-eyed position, instead of parallelism, of the visual axes. Dynamic convergence can take place within the zero, but divergence beyond the zero is only possible to a very limited extent. When one eye is better than the other it becomes the fixing eye and the squint is monolateral. When both are of equal value the squint is frequently alternating.

Squints are commonly divided into: (1) occasional; (2) constant monolateral; and (3) alternating.

1. *Occasional squints.*—These, which are sometimes incorrectly called "periodic" squints, arrange themselves into two distinct groups which we may call (*a*) true occasional squints, and (*b*) premonitory occasional squints. True occasional squints occur under all sorts of conditions. Some patients squint only in near vision, some on looking down, some under the influence of any strong emotion some without any evident exciting cause. In many cases there is considerable refractive error, the optical correction of which usually, but not always, relieves the condition I have notes of a few cases (which may properly be called periodic) in which the squint has manifested itself every alternate day as regularly as a tertian ague. As a rule, the vision is good in both eyes. The majority of patients, but not all, have some slight degree of binocular vision when the squint is not manifest. When the deviation is present there is diplopia in some cases in others the vision of the deviating eye is temporarily suppressed. A true occasional squint may disappear spontaneously or it may maintain its character unchanged throughout life. Cases of the second group, premonitory occasional squints, are simply the precursors of constant monolateral squints. Premonitory occasional squints become constant after lasting usually from two to six months During the occasional stage optical correction will in the majority of cases, but not by any means in all, prevent this change and cure the squint.

2. *Constant monolateral squints.*—In constant monolateral squints the deviation is constantly present and is always manifested by the same eye, though the angle may vary.

3. *Alternating squints.*—Alternating squints are those in which, though there is always an abnormal convergence of the visual axes, the patient is able to fix, and to maintain fixation, with either eye at will without covering the other. Alternating squints suffer much less than monolateral squints from neglect or inefficient treatment, because each eye is used in turn. But it is far more difficult to get a perfect cure in a case of alternating squint The reason is not far to seek. In a case of alternating squint the visual acuity is usually good in each eye, the refraction of each eye is usually very nearly the same, and in many cases there is little or no refractive error. If such a pair of eyes become dissociated it means that the fusion faculty is in a very rudimentary condition. As a matter of fact, in these cases it sometimes appears to be congenitally absent, so that training with the amblyoscope, even as early as at three and a half or four years of age, fails to develop even the lowest grade of binocular vision. Of all constant squints about 89 per cent. are monolateral and 11 per cent. are alternating.

The age at which the deviation first appears.—Of the 1278 cases under consideration I was able to make out with some approach to accuracy the age at which the deviation first appeared in 809 cases:—Before one year of age, 102 cases, or about 12½ per cent.; between one year and two years, 142 cases, or about 17½ per cent.; between two and three years, 195 cases, or about 24½ per cent.; between three and four years, 159 cases, or about 19½ per cent.; between four and five years, 91 cases, or about 11 per cent.; between five and six years, 58 cases, or about 7 per cent.; and after six years of age, 62 cases, or about 7½ per cent. It will thus be seen that in 74 per cent. of the cases the deviation appeared before the end of the fourth year and in only 7½ per cent. was its appearance delayed until after the end of the sixth year.

At the first appearance of a monolateral squint there is often a considerable degree of congenital amblyopia in the deviating eye, and occasionally in the other eye also But the deviating eye *always* at first has the power of fixing when the other eye is covered. If the case is left to take its own course, or if the child receives merely the usual routine treatment with glasses, in the great majority of cases the deviating eye becomes blinder—there is an amblyopia from disuse superadded to any congenital amblyopia which may be present. In a considerable proportion of the cases, after a time the deviating eye loses the power of central fixation. Its visual acuity is then reduced to the counting of fingers. This loss of central fixation is especially prone to occur in young squinters. So much so that there is a widespread belief, even among ophthalmic surgeons, that an eye which deviates during the first 12 months of life is necessarily very blind. Yet this is not the case. Of the cases which I saw within six months of the first appearance of the deviation I do not find the young squinters especially amblyopic. It is true that in about 30 per cent. of constant monolateral squints treated by glasses alone the eyes eventually become "straight," but in the majority even of these cases considerable damage is done before this result is attained.

The spurious squint of infants.—During the first few months of life, when the muscular and visual coordinations of the eyes are in a very rudimentary condition, it often happens that the eyes momentarily converge or diverge in response to some gastric or other disturbance This is of no importance. If, however, the deviation lasts several minutes, or if one eye deviates while the other steadily fixes some object, and more especially if the deviation is always exhibited by the same eye, the case is one of true squint and demands treatment without delay.

ETIOLOGY.

The one essential cause of squint is a defective development of the fusion faculty. This is frequently associated with other developmental defects, such as an abnormal shortness of the eyeball (hypermetropia) and congenital amblyopia Hypermetropia, anisometropia, and congenital amblyopia may any or all be present, but with a normal fusion faculty there will be no squint Or the fusion faculty may alone be defective or even congenitally absent, in which case there is usually an alternating squint with perfect vision in each eye

A hypermetrope, to see distinctly, must use his accommodation, even in distant vision Normally an effort of accommodation has associated with it a convergence of the visual axes In this way hypermetropia causes a *tendency* to abnormal convergence, but is not in itself sufficient to cause squint If, however, the fusion faculty be defective the patient is ready to squint on slight provocation The abnormal hypermetropia often associated with a defective fusion faculty may supply this provocation Or the immediate exciting cause may be a sudden fright, a blow on the head, or, commonest of all, the violent straining of whooping cough How these upset the equilibrium of the converging mechanism I do not know, but they are powerless in the presence of a normal fusion faculty I have been fortunate enough to see several children, who have begun to squint later than usual, within a few days of the commencement of the deviation In many of these cases I have examined the fusion faculty with the amblyoscope and have always found it ill developed

CASE 1 —A boy, aged five years and two months, was brought to me at the West Ham Hospital He had a monolateral squint which first appeared six days before I examined his fusion faculty which I found very defective. I got the mother to bring three other children who did not squint In two of these children the fusion faculty was normal, in the other, a boy, aged four years and one month, it was very poorly developed I told the mother that this child would very likely squint, 11 weeks afterwards he was brought to me with an alternating squint, which appeared after a severe scald from trying to drink from the spout of a teapot I have since been able to examine a younger child in the same family and, having found the fusion faculty normal, I have ventured to promise the mother that this last child will never squint

Congenital amblyopia and anisometropia predispose to squint by lessening the value of binocular vision Heredity is a very strong predisposing cause of squint In the 1278 cases under consideration I was able to get some family history in 1028 cases Of these there was a history of squint in father, mother, brother, or sister of the patient in no less than 527 cases, or about 51 per cent

TREATMENT

In the treatment of convergent squint four objects should be kept constantly in view (1) to prevent the loss of central fixation in the deviating eye, (2) to prevent deterioration of vision of the deviating eye, (3) to train the fusion faculty at the earliest possible age, and (4) to restore the visual axes to their normal relative directions

Take first the case of an infant with a constant squint After measuring the angle of the squint and ascertaining the refraction by retinoscopy under atropine, glasses, fully correcting the hypermetropia and astigmatism, are ordered, if possible, to be worn constantly The age at which glasses will be tolerated depends to a certain extent upon the disposition of the child, but chiefly upon the degree of refractive error A child whose hypermetropia and astigmatism combined amount to 4 D or 5 D will usually wear glasses well as soon as he is able to crawl It then becomes chiefly a question of the skill of the optician in fitting the frames At the Royal London Ophthalmic Hospital (Moorfields) I have sent Mr Hawes many children under 12 months of age and he has always managed to make frames which will stick on Of course these young children sometimes break their glasses but I have never known a case in which the eye has been injured

Next, in order to exercise the deviating eye, and so to prevent deterioration of vision or loss of the power of fixation in this eye, I order one drop of liquor atropinæ to be put every morning *in the ' straight" eye only* to abolish its power of accommodation The child will then continue to use the (atropised) fixing eye for distant vision But in looking at anything close at hand he quickly learns to use the squinting eye in which the power of accommodation is not interfered with In this way amblyopia from disuse is avoided and central fixation is preserved in the deviating eye The drop every morning in the fixing eye only is used for the first 14 days in each month till the deviation is cured or the child is old enough for exercises with the amblyoscope Of course, covering up the better eye for four hours or so every day would do as well, but very few parents will take the trouble to do this for years at a time, to say nothing of the inconvenience to the patient A common practice with many surgeons, and one invariably recommended in books, is to order atropine for *both* eyes for months at a time, for squinters who are supposed to be too young for glasses This is wrong in principle and worse than useless in its results. Atropine never brings about a permanent cure of the squint, but in some cases it causes a temporary cessation of the deviation These last are just the cases in which a pair of glasses given early, would be likely to effect a cure Moreover, the deviating eye is usually the more hypermetropic, so that to paralyse its accommodation with atropine is the very way to insure that this eye shall never under any circumstances be used

Next consider a neglected case in which acquired amblyopia or even loss of central fixation in the deviating eye has been allowed to occur Usually not much improvement can be got when the damage has once been done One often, however, sees a slight improvement in the vision of the deviating eye after the shade or atropine has been used for the fixing eye for some time Now and then one gets a considerable improvement When central fixation has been recently lost in the deviating eye, if this eye wanders without taking up any definite position of false fixation, continuous occlusion of the better eye for two or three weeks will sometimes restore its fixation power If, however, the deviating eye takes up a definite position of false fixation the case is quite hopeless

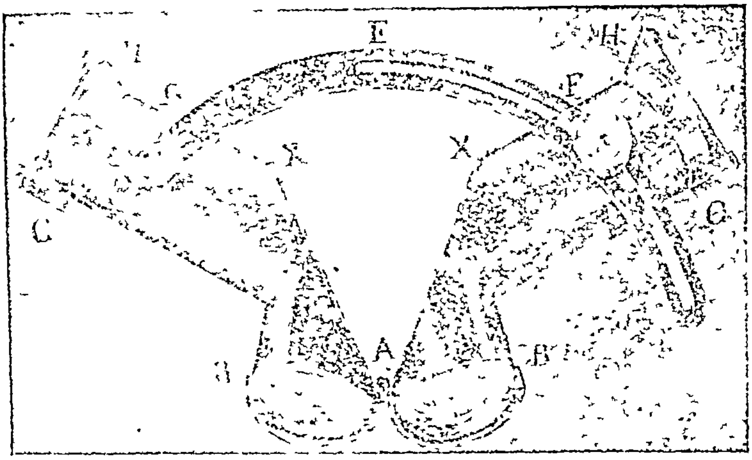
CASE 2 —A boy, aged six years, whose right eyeball had been ruptured by the end of a gas pipe, was brought to me The eye had to be excised The left eye had squinted inwards since the age of two years, and fixation was lost It is now four and a half years since the accident to the good eye and the enforced use of the amblyopic eye during this period has produced no improvement He can only count fingers at a distance of eight feet

Of cases which are treated by glasses alone in about 30 per cent the deformity eventually disappears But even in these cases the deviating eye often becomes very blind in the interval And even in the cases in which some sort of binocular vision is picked up *a la grâce de Dieu* it is usually of such a feeble kind that glasses must be worn throughout life for fear of a return of the deviation So that optical correction, though a most useful auxiliary, is very unsatisfactory as the sole means of treatment

The rational method of treatment is to endeavour to remove the cause of the squint by training the fusion faculty at an age when binocular vision should normally be developing There are three great difficulties in the way of fusion training in these young children (1) the vision of the deviating eye is "suppressed," so that although the sight of this eye may be perfect the patient is unable to use it except when the other eye is covered, (2) the angle of the squint is usually so great that even if there were no suppression both eyes could not at the same time look into an ordinary stereoscope, and (3) these young children will only submit to the treatment so long as they find it interesting

In 1895 I made the tin instrument which I show you to-night The other instruments shown are brass copies of the original made for me by Mr Hawes of 79, Leadenhall street, London, E C I have called it ' Amblyoscope"—an instrument by means of which an amblyopic eye is trained to take its share in vision (Fig 1) The instrument consists of two halves joined by a hinge at A, in the diagram Each half consists of a very short tube joined to a longer tube at an angle of 120 degrees. At A X is an oval mirror At G H in each tube, is placed a small glass object slide At A B is a lens, the focal length of which equals the distance of the reflected image of G H In addition to these lenses there are slots at A B into which other lenses from the trial case may be put, to correct the refractive error of the patient The two halves of the instrument can be brought together to suit a convergence of the visual axes up to 60 degrees or separated to suit a divergence of as much as 30 degrees The pairs of object-slides are drawn on translucent paper stuck on glass slips These are of three classes The first class consists of pairs of devices such as a clown and a hoop, a mouse and a trap, &c These require no blending of images but only simultaneous vision. The second class consists of devices, part of which are on each slide, so that a blending of the images must take place in order that the full picture may be seen. The third class consists of stereoscopic pictures which, when combined, give an impression of the third dimension.

FIG. 1.



The Amblyoscope.

The methods of vision-testing and of investigating and training the fusion sense in young children I have gone into much more fully in a paper read before the Ophthalmological Society of the United Kingdom, so I shall only refer to it very briefly now. Take as an example a young child whose deviating eye has not much less than one-fourth the visual acuity of the fixing eye. I take the child on my knee and adapt the amblyoscope roughly to the angle of his convergence. The instrument is then held before the child's eyes and an electric lamp is put in the axis of each tube about four feet away. By a simple mechanical arrangement each lamp is easily brought nearer to, or put further away from, the tube which it illuminates (ordinary paraffin lamps will do just as well). A slide showing a hoop, for instance, is put in the tube before the child's fixing eye and a clown in that before the squinting eye, and the child is told what to look for. At first he sees only the hoop. The lamp before the fixing eye is then taken further away, and that before the squinting eye is brought nearer until the child sees the clown. By this time he has lost sight of the hoop. The intensities of the illuminations are then readjusted until the child sees both the clown and the hoop. The child is then allowed to grasp the instrument and, assisted by the hands of the surgeon, is taught to vary the angle of the instrument so as to make the clown go in and out of the hoop. Many other similar pairs of slides are then shown. An ordinary child of three and a half or four years of age takes a very keen interest in this game which he imagines to have been invented merely for his amusement. Devices which require a true blending of the images are then shown. After a time it is often found that the angle of the instrument may be altered to a very considerable extent, either in convergence or divergence, while the eyes follow the objects and maintain fusion of the pictures. Often one gets a very powerful "desire" for binocular vision in these young subjects with surprising facility. The next step is to equalise the intensities of the lights. This may usually be done at this stage without a return of the suppression. In many cases one is able to diverge the two halves of the amblyoscope more and more at each visit till the deviation disappears entirely. In other cases operation may be necessary. If, then, the eyes are put approximately "straight" the desire for fusion will fill up any slight gap that may remain. However the actual remedying of the deviation be effected, if the child has this powerful "desire" for fusion (which can only be acquired in early childhood) a perfect cure of the squint results. The child will then in most cases be able after a time to lay aside his glasses except for reading.

The special points of the amblyoscope are: (1) it is adapted for use during the continuance of a squint of any degree; (2) the suppression of the vision of the deviating eye is quickly overcome by the unequal illumination of the object-slides, instead of by the slow and painful method, recommended by Javal and others, of continuous occlusion of the better eye for months or a year at a time; and (3) the variety of the pictures amuses and interests the child, so that he will give all the help he can.

OPERATION.

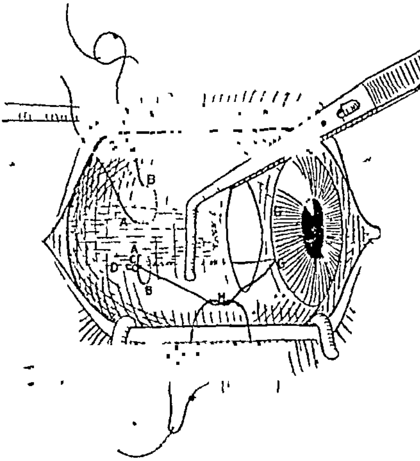
Age.—If I am unable to get binocular vision I do not usually operate before the age of eight or nine years. If, however, exercises with the amblyoscope have produced a strong "desire" for fusion I have no hesitation in operating at any age. Operation is *indicated* when the periodic measurements of the angle of the deviation show that this is either not decreasing or is decreasing only very slowly. The dynamic convergence should always be examined. If the fixing eye, after looking at a distant object, suddenly fixes a nearer object the deviating eye will roll still further inwards, a dynamic convergence being superadded to the abnormal static convergence. If the dynamic convergence is very deficient simple tenotomy is strongly contra-indicated. If binocular vision cannot be obtained, and a removal of the deformity is all that can be hoped for, and if dynamic convergence is good, it does not matter so much what operation is done; though the wide palpebral fissure and slightly proptosed eye often seen after tenotomy do not improve the personal appearance of the patient. But if I have been able to develop the fusion faculty and I expect to get binocular vision after operation, I never do a tenotomy except in combination with an advancement. I once used to tenotomise these cases sometimes for want of beds. Several of these patients have since suffered from insufficiency of convergence and pain in the eyes in near vision.

The operation of advancement of a rectus muscle.—The great cause of failure in this operation is the difficulty of getting the sutures to hold. With practice one can make sure of getting a firm hold of the tough fibrous tissue at the margin of the cornea without putting in the needle dangerously deep, so that this end of the suture does not tear out. The difficulty is with the end which is attached to the muscle. After trying extensively many different advancement operations I found that two gave better results than the others. In one, three or four sutures are simply passed through the tough circumcorneal tissue and through the muscle. If these sutures hold for a week the results are permanent. But the muscle end very often cuts its way through in three or four days. In the other operation the sutures are knotted on the muscle either in one or two parts. This nearly always gives good *immediate* results, but a very large proportion of the cases relapse within six months. I think that this is probably due to the fact that the muscle atrophies in front of the ligatures, and so is only attached to the globe by its lateral expansions.

The author's advancement operation.—I devised the following operation with the object of combining the advantages and avoiding the disadvantages of the two operations to which I have just referred (Fig. 2). The ordinary advancement instruments are required: a speculum, a pair of straight blunt-pointed scissors, a fixation forceps, Prince's advancement forceps, a needle-holder, very sharp curved needles, and thread, and, if a tenotomy is to be done at the same time, a squint-hook also. For the suture material I use black silk prepared as follows. After sterilising and drying, the silk is steeped for a few minutes in very hot melted paraffin wax to which a little vaseline had been added. The thread is then drawn tightly through a sterilised rag and is kept in bottles ready for use. The black silk is easily seen. The waxing makes it practically non-absorbent and stronger and more compact, so that it can be more easily threaded. It gives the silk just sufficient stiffness to prevent its tying itself into undesired knots during the operation, without making it harsh.

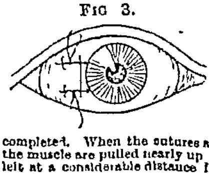
The patient may be anæsthetised or, for older patients, cocaine may be used. A drop of suprarenal extract, used from time to time, facilitates the operation by making it bloodless. The surgeon, standing behind the patient's head, seizes the conjunctiva with the fixation forceps about a quarter of an inch from the margin of the cornea and below the level of the tendon. A small opening is then made in the conjunctiva with the scissors. The sub-conjunctival tissue and capsule of Tenon are then seized with the forceps and an opening is snipped through them with the scissors. The female blade of a Prince's advancement forceps is introduced through the opening and passed beneath the tendon, the male blade being superficial to the conjunctiva The forceps is then closed. The conjunctiva, the capsule of Tenon, and the tendon are thus firmly clamped together by the forceps while their relations are yet undisturbed. The conjunctiva and the capsule are then divided vertically for nearly half an inch close to the margin of the cornea The tendon is divided at its insertion One of the needles is then passed inwards at A, through the conjunctiva, the capsule, and the muscle, and is brought through to the under side of the muscle It is then passed again through the muscle, the capsule, and the conjunctiva and brought out at B. The bight of the thread thus incloses about the lower fourth of the width of the muscle, together with its tendinous expansions and capsule and conjunctiva. The other needle is similarly entered at A′ and brought out at B′, the bight of the thread inclosing the upper fourth of the width of the muscle, &c The ends of the thread from A′ and B′ are then knotted tightly at O. The end bearing the needle is then entered at D and is passed through the conjunctiva, the capsule, and the muscle, and then carried beneath the lower blade of the Prince's forceps nearly to the corneal margin. The needle is here passed through the tough circumcorneal fibrous tissue and brought out at G The two ends of the thread are then temporarily tied loosely with a single hitch at H The first suture is then similarly dealt with The anterior part of the muscle and the overlying capsule and conjunctiva are then removed by cutting them through with scissors, beyond where they are grasped by the Prince's forceps. The gap is then closed by tightening and securely tying each suture at H, H, so that the anterior end of the muscle is brought nearly up to the corneal margin at G, G. Any desired degree of rotation of the eyeball may be obtained, according to the position of A, B, C A firm, unyielding hold is got for the sutures at each end. The anatomical relations of the muscle are disturbed as little as possible, and its blood-supply is not interfered with The immediate effect seen under cocaine or after recovery from a general anæsthetic is the final result. So far, I have had no relapse with this operation

FIG 2



Diagrammatic view of the advancement operation

FIG 3.



The operation completed. When the sutures are finally tied the knots on the muscle are pulled nearly up to the corneal margin, not left at a considerable distance from it as the diagram incorrectly represents.

These methods of treating a case of convergent squint may seem somewhat tedious. But surely no one will grudge the time and trouble if he realises that the whole future career of the patient often depends upon the skill and care of the surgeon who first sees the case.

CASE 3—In November, 1899, a brother and sister were brought to me suffering from convergent squint—the eldest child, a boy, aged eight years, and the fourth child, a girl, aged two years and seven months The boy had begun to squint when he was two years old. He was then taken to a surgeon, who ordered atropine for both eyes for some months At the age of three and a half years the boy was ordered to wear glasses. He has worn glasses ever since When I saw him, at the age of eight years, he had a slight convergent squint in the left eye of seven degrees with his glasses The squint was quite masked by the angle gamma. But the squinting eye had lost all power of fixation and its vision was reduced to the counting of fingers at a distance of four feet This boy will of course be debarred from entering the profession of arms for which he was intended.

CASE 4—The sister of the patient in Case 3 was two years and seven months old when I first saw her She had convergent squint in the left eye of 38 degrees. The fixation of the left eye was wandering and uncertain but was not quite lost After retinoscopy under atropine glasses were ordered. Continuous occlusion of the right eye for 14 days resulted in quite steady central fixation in the left eye A drop of liquor atropinæ was then ordered to be put in the right eye *only* every morning and the shade was discontinued The child immediately learnt the trick of using the (atropised) right eye for distant vision and the (unatropised) left eye for looking at near objects She has used atropine, for the right eye only, for the first fortnight in each month ever since Three months ago I began exercises with the amblyoscope Her fusion faculty was easily and quickly developed to a very potent degree. The angle of the deviation is now 16 degrees and the ivory ball test shows that the vision of the deviating eye is at least equal to $\frac{6}{12}$. Operation may or may not be necessary—most probably not. In any case there will be a perfect cure of the squint with the highest grade of binocular vision, and in all probability she will be able later to dispense with her glasses except for near work

It is not quite certain that the boy would have fared as well as the girl had he received similar treatment soon after the squint showed itself, though it is extremely probable. But this is certain—if the girl had had no more done for her than the boy she would have been now in the same deplorable condition

The family practitioner is in most cases consulted about squint, or he notices it himself, soon after its first appearance. The responsibility then rests with him to see that the child receives efficient treatment *early*. Unless he has sufficient time and knowledge of ophthalmology to treat the case himself he should see that the child is taken to an ophthalmic surgeon or hospital without delay. If some delay should be unavoidable he can at least order a drop of atropine to be put in the fixing eye only every morning.

Harley-street, W.

UNIVERSITY OF BIRMINGHAM: APPOINTMENT OF EXTERNAL EXAMINERS—At a meeting of the University Council on May 1st, the Vice Chancellor (Alderman C G. Beale, M A) presiding, the following appointments of examiners were made among others:—Physics, Professor J J. Thomson, F R S, Chemistry, Professor H. McLeod, F R S; Zoology, Dr S F Harmer, F R S.; Botany, Professor Reynolds Green, F R S; Philosophy, Mr. J. F. Stout; Anatomy, Professor Alexander Macalister, F R S.; Physiology, Professor John Grey McKendrick, F.R S.; Pathology, Professor G. Sims Woodhead, F R S Edin; Medicine, Dr. Donald MacAlister; Surgery, Mr. W. H. A Jacobson; Midwifery and Gynæcology, Dr. Berry Hart; Forensic Medicine and Toxicology, Dr. A Pearson Luff; Public Health, Dr. George Reid; Dental Subjects, Mr. Charles S. Tomes, F R S; Clinical Medicine, Dr. T. Stacey Wilson; and Clinical Surgery, Mr W. F. Haslam.

DISEASES OF THE MAXILLARY ANTRUM, THEIR SYMPTOMS, CAUSES, AND TREATMENT.[1]

BY ADOLPH BRONNER, M.D., M.R.C.S.,
SENIOR SURGEON TO BRADFORD EYE AND EAR HOSPITAL; LARYNGOLOGIST TO BRADFORD ROYAL INFIRMARY.

THE subject of my paper to-night—diseases of the maxillary antrum—is one in which I have for the last 15 years had a good deal of experience; and in numerous cases I have had the pleasure of working with members of your profession.

The maxillary antrum or sinus, or "antrum of Highmore," is of pyramidal shape and is situated above the molar teeth and below the orbit. In the fœtus the antrum is very small—in the fourth fœtal month it is only one third of a millimetre in size, in the fifth month it is about five millimetres—and it is round in shape. It lies high up above the unerupted teeth. It remains small up to the fifth or the sixth year, when it rapidly increases in size and alters its shape. In the seventh year it is fairly large, of pyramidal shape, and it lies lower down, just above the roots of the molar teeth. These facts are of great importance from a surgical point of view. Up to the sixth or the seventh year the antrum should be opened through the middle nasal meatus and not through the alveolus. The size and position of the antrum in adults, however, vary very much, even in the same individual. They depend on the amount of bone-absorption in the upper jaw and on the size and shape of the nares. If the nasal cavity is large it naturally encroaches on the antrum. In opening up the antrum we have to take all these facts into consideration, and the operation is not so easy and simple as some people seem to think.

Of the walls of the antrum only two, the inner and the lower, concern us this evening. The inner wall is, of course, the outer wall of the nasal cavity. It is bony, with the exception of one part which consists only of mucous membrane. This lies between the middle and lower turbinated bones. In it are situated the normal openings—the maxillary and the so-called accessory ostium. The former lies further forward and higher than the latter. The lower part of the antrum is contained in the alveolar process. It varies very much in size and position. Generally it extends down to the roots of the molars. Often these are covered only by a very thin layer of bone which frequently is pressed upwards by the tooth and in part projects into the antrum. Often there is a *thick* layer of bone between the teeth and the antrum. If the lower portion of the antrum is broad, we call the parts the "alveolar sinus" and the "palatine sinus" respectively. The lining mucous membrane of the antrum is directly continuous with that of the nose through the maxillary and accessory ostia.

The commonest disease of the antrum is the so-called empyema or purulent catarrh of the lining mucous membrane. Cases of acute empyema were very rarely met with before the recent epidemics of influenza. Since then they have been fairly common. Sometimes they follow scarlet fever. The symptoms are generally well marked—severe pain, neuralgic or throbbing, which increases on pressure or rapid movements of the head. The pain is generally intermittent and depends greatly on the amount of fluid in the antrum. When this escapes through the ostia the pain subsides, but returns again as soon as the serum or pus accumulates. The teeth are often painful, especially on pressure. This gives rise to the erroneous idea that the teeth are diseased and are the cause of the empyema There is generally rise of temperature. The cases mostly heal spontaneously without operative interference. In the two cases which I have seen, however, I opened up the antrum at once and the distressing symptoms soon disappeared.

Chronic empyema of the antrum is extremely common. It is generally not diagnosed. In fact, in many cases the patient does not complain of any symptoms and the empyema is only discovered at the post-mortem examination. The old-fashioned idea (which I am sorry to say is still very prevalent) that empyema of the antrum gives rise to most distressing symptoms, such as distension of the cheek, severe pain, &c., is absolutely wrong. These cases are rare and they are generally the result of a long-standing and neglected empyema. Of course, cases of syphilitic or tuberculous disease of the antrum do give rise to grave symptoms. As a matter of fact the subjective symptoms are very slight. There is often recurrent infra-orbital neuralgia or a dull aching pain in the cheek, accompanied by swelling of the soft tissues. More frequently there is pain over the nose and orbit. This fact is of great practical importance, as disease of the frontal sinus is often wrongly diagnosed. I know of several cases of empyema of the antrum which, because of the orbital pain, were diagnosed as, and treated for, frontal sinusitis. The most common complaints are neuralgia, a blocking of one nostril, unilateral "cold in the head," a nasal discharge, or a bad smell in the nose. Often only one of these symptoms is present. I have already published[2] three cases of empyema of the antrum, in which a bad smell in the nose was the only symptom complained of. The discharge or the smell is more marked when the patient bends the head forward or on one side. If the accessory ostium is large and open the pus flows to the back of the nose into the throat and the patient complains of a bad taste and a dry throat. Some months ago I saw a medical man who suffered from recurrent unilateral tonsillitis and a bad smell in the nose. There was empyema of the antrum. When this was cured there was no return of the tonsillitis or of the bad smell. Often the constant irritation caused by the pus gives rise to polypi or enlargement of the middle turbinated bone. In all cases of unilateral discharge from the nose the antrum should be explored. Of course, the pus may also come from one or more of the other accessory sinuses, from the ethmoidal and sphenoidal cells or the frontal sinus. In cases of ozæna the antrum is often affected, and it is obviously impossible to cure the ozæna until the antrum has been treated. These are the cases of so called incurable ozæna. The objective symptoms are also often very indefinite. Generally, there are hypertrophy or polypi of the mucous membrane of the middle nasal meatus or there is a small crust of dried muco-pus under the middle turbinated bone. When this is removed a few drops of pus escape. Often there is no crust, only pus which sometimes pulsates. This is an almost certain sign of empyema of the antrum. Of course when the antrum is empty, or the ostia are blocked, no pus can escape. In the old and some of the new text-books distension of the cheek is given as a sign of empyema of the antrum. This is absolutely wrong. These are cases of cysts and not of empyema The inner nasal wall of the antrum sometimes bulges inwards when there is much pus and the ostia are blocked. Rarely there is distension downwards towards the hard palate. I have only seen three or four of these cases. The only way of making a reliable diagnosis is to puncture and to wash out the antrum. This is generally done with a Lichtwitz trocar. The opening is made in the lower meatus, about three centimetres behind the anterior part of the lower turbinated bone, and just under it. If made too low down the puncture is difficult and painful, as the bone is often very thick there. If cocaine or eucaine is applied a few minutes before operating, there is little or no pain. Warm sterilised water is injected through the trocar. It escapes through one of the ostia. If it is clear, of course there can be no empyema. If the ostia are blocked you must make a counter-opening or use a double trocar. As I mentioned above, the antrum is often very small or practically non-existent, and this explains why in some rare cases it cannot be found with the trocar. Out of the many cases which I have punctured with the trocar I have only been unable to find the antrum in four or five. I may add that in all cases of purulent nasal discharge (which are extremely common) and in cases of obstinate ozæna, I always, when possible, syringe out the antrum for diagnostic purposes. It is very difficult, often impossible, to wash out the antrum through the maxillary ostium. It is also dangerous, as there is a possibility of wounding the orbit, as in some cases the orbit lies very near to the middle meatus. Transillumination is often used to find out if the antrum is diseased. A small electric lamp is placed in the mouth, the lips are closed, and the room is darkened. The cheek and lower orbit, and often the pupil, appear of a rosy red colour. If one antrum is diseased, that side is darker than the other. We know, however, that the size of the antrum and the thickness of bone, even in the same person, vary very mu indeed, so that transillumination is of no very great val Sometimes by using Politzer's bag there is an escape of p from the antrum. But this does not happen in all cas The so-called "hydrops" of the antrum, as described in old text-books, does not exist These are cases of cysts. Polypi in the antrum are fairly common, as proved by post-mortem examination, but they do not always give rise to subjective symptoms Sometimes, however, they block the ostia and prevent the passage of serum or pus and of air in and out of the antrum.

---

[1] A paper read before the Leeds section of the Midland Branch of the British Dental Association on March 19th, 1901.

[2] THE LANCET, July 17th, 1897, p. 144.

Now about cysts. These are not very common and they are mostly of dental origin. We know very little about their pathology. I had intended to discuss this matter thoroughly this evening, but I could not get the specimens I had hoped to procure, nor could I find much reliable literature on the subject. There are, roughly speaking, two kinds of dental cysts, those caused by retention of unerupted teeth and those due to inflammatory changes in the root-membrane of an already erupted tooth In the first class the tooth is generally contained in the cyst It is often difficult to diagnose between empyema and a cyst. A large cyst causes distension of the cheek, and on pressure you hear a peculiar crackling noise. If you inject water into the cyst, it does not pass out through the nares, as it would if injected into the antrum.

Tumours of the antrum are frequently met with The most common is carcinoma. The first symptoms are severe pain in the cheek and nasal discharge. You generally find nasal polypi. These bleed freely on removal. If diagnosed early and if the whole of the upper jaw is removed (this is absolutely necessary) the prognosis is fairly good I saw a well-known man of this town some seven years ago. He complained of unilateral nasal obstruction and epistaxis; there was not very much pain On removing numerous polypi, I found a large opening into the antrum which was filled with a red soft growth The upper jaw was removed by Mr. E Ward, of Leeds, and the patient is still alive and occupying an important official position.

The question of causation of empyema of the antrum is still a much disputed point. Formerly it was thought that most cases were due to diseased teeth. This, however, is not the case. Anatomists maintain that the empyema is very rarely of dental and nearly always of nasal origin. Zuckerkandl, the greatest authority on the anatomy of the face, examined 300 cases of empyema of the antrum in the post-mortem room and in only one case could a direct connexion between the teeth and the empyema be found. Of course there may have been, and probably were, several cases in which an existing connexion could not be, or was not, traced at the post-mortem examination. The dental origin can be two-fold—disease of the tooth root (with or without abscess) or alveolar periostitis. We know that often the roots of the premolar or molar teeth practically touch the thin floor of the antrum, in some cases they even project into the cavity. Considering the large number of persons who suffer from diseased teeth it is very remarkable that relatively so few cases of antral disease are met with and that the direct connexion cannot be traced anatomically. We know also that after extraction of molar teeth a probe can often easily be passed into the antrum; and yet disease of the antrum following this operation is very rare.

Empyema of nasal origin can be due either to a direct extension of disease of the mucous membrane of the nares through the maxillary or accessory ostium into the antrum; (for we know that the membrane of the two cavities is directly continuous), or particles of mucus and pus or any foreign body containing micro organisms can be blown into the antrum through the ostia, when the patient blows his nose, and set up inflammation there. In some cases (perhaps a large number) the ostia become blocked by hypertrophied mucous membrane or by a polypus. As can readily be understood this must give rise to disease of the lining membrane of the antrum During the last 15 years I have seen many cases of empyema of the antrum. In every case I have tried to trace the origin of the disease, and only in very few have I been able to find any direct connexion with a diseased tooth or teeth.

The methods recommended for treatment of empyema of the antrum are numerous. The points to aim at are (1) to open the antrum at the lowest possible point, so as to get good drainage of the cavity, and (2) to keep this opening patent till the disease has been cured. Cases of acute empyema generally heal without surgical interference. In

meatus is not low enough to secure proper drainage. The simplest and most effectual method is to make an opening into the antrum through the alveolus. I also always make a counter-opening through the lower meatus The fact that in most cases one or more of the premolar or molar teeth are missing or diseased simplifies the operation. Numerous burrs and drills have been recommended for perforating the alveolar process. As the size and position of the antrum vary very much it is necessary to be very careful, as there is danger of penetrating into the nose or the orbit. The cavity should be washed out. The nature of the discharge often gives us an idea as to the extent and character of the inflammation In many cases the operation can be performed with cocaine or eucaine (beta). I generally apply a little powdered eucaine and cocaine to the parts and then inject about 10 minims of a solution (1 per cent) of eucaine. The latter is less liable to give rise to toxic symptoms than cocaine. The fistula readily closes up and it is in all cases absolutely necessary to keep it open for several weeks or even months, till the diseased mucous membrane of the antrum has been cured. A metal tube or solid plug should be introduced a day or two after the operation. This can be fixed on to the adjoining tooth or teeth; or if the patient wears a plate, attached to this If a tube is used it is generally supplied with a revolving plate or a cap or plug of some kind, to prevent the entrance of food into the antrum. Personally, I do not think that it is always necessary to block the tube. Food does not readily enter in any large quantities, and if it did it would come away when the cavity was washed out Mr W J England, of Cavendish square, London, has kindly sent me a pattern of the tube which he generally uses.

The after treatment is of great importance. In most cases the tube is removed and the treatment stopped much too soon. The cavity should be washed out from two to four times a day with a hot antiseptic solution, as long as there is any discharge; that is, until the water which passes out through the nares is quite clear and contains no pus or mucus. For at least from four to six weeks longer the tube should be kept in position and the cavity syringed out once a day. I always also use insufflations of aristol and boric acid from two to three times a day; at first in very large and then in small quantities. This shortens the treatment very much If at the end of from four to five weeks the secretion of pus has not ceased, there will probably be a polypus in the antrum or some disease of the bone. The opening should then be enlarged so as to admit a finger and the cavity should be carefully explored. If the alveolus is not large enough it becomes necessary to make a large opening through the canine fossa An incision is made through the mucous membrane, this is deflected and a large piece of bone is removed with the chisel. The cavity is well scraped out with a sharp spoon and plugged for several days with gauze. Many surgeons open up the antrum through the canine fossa in ordinary cases The advantages of this method are that the pus from the antrum does not drain direct into the mouth, that there is no danger of food entering through the opening, and that the tube is easily kept in position by the lip Personally, I prefer the alveolar method and only open up through the canine fossa when the teeth are all sound or when I think that there is a polypus or some carious bone in the antrum When there is a cyst this should be extensively opened, the lining membrane scraped, and the cavity allowed to heal up by granulation. In large cysts we often have to excise part of the bony wall. It is remarkable how quickly the parts regain their normal shape and how little deformity remains.

Bradford.

NOTIFICATION OF MEASLES.—The Sanitary Committee of the Exeter City Council have recently inquired into the advisability of the notification of measles and have taken the opinion of the five district medical officers upon the subject. At the meeting of the city council on April 27th the committee reported that acting on the advice of four out of the five medical officers they had decided to recommend that measles be not included in the list of notifiable diseases The recommendation was adopted by the council.

MENTAL FATIGUE IN SCHOOL-CHILDREN.

BY DR. JOSEPH BELLEI,
OF THE BOARD OF HEALTH, BOLOGNA, ITALY.

ONE of the most important problems connected with the general question of the education of the young is the determination of the relations existing between the daily instruction given in the schools and the fatigue that is thereby caused, so that a way may be found of imparting knowledge without danger to the physical and mental health of the children.

As one of the medical officers attached to the public schools of Bologna I have endeavoured to study the phenomena of mental fatigue in several children who were under my care, so that I might perhaps contribute in some degree to the solution of a problem which is in itself of great importance, and, moreover, has not received in Italy the attention which it deserves. Many are the methods used to determine the degree of mental fatigue. They can be divided into (1) those which attain their end in an indirect manner—viz., through experiments on the sensibility of the skin, on the amount of muscular fatigue, &c.; and (2) those which draw their conclusions from the direct examination of the mental work done by the children at a given moment. These last can be classified as follows:—

1. *The dictation method.*—The children at a given moment are set to write from dictation an article of a definite length, the character of which is well within the range of their mental capacity. The number and nature of the mistakes that are made are taken as the index of the quality of the work and therefore of the mental fatigue at the moment.

2. *The method of memory.*—The teacher repeats to the children with a definite rapidity a series of numbers which they have to write down in the same order. One can judge of the mental fatigue from the greater or less number of figures that the children have taken down in order.

3 *The arithmetical method.*—This method consists in giving the children exercises in addition, multiplication, &c., or easy problems of algebra to do at a given time.

4 *The method of combination*—Ebbinghaus has proposed a special method of studying the mental capacity of children. He believes that it can be adapted also for the determination of mental fatigue, but I think that for this latter purpose Ebbinghaus's method is useless.

I pass over the methods by which mental fatigue is estimated in an indirect manner, because it is impossible to employ them on many persons at the same time. Which is to be preferred among the methods by which mental fatigue is estimated from the quality of the mental work? I think that in order to form an exact idea of school-children's mental fatigue at a given moment it will be sufficient to estimate the attention that they can give to a subject at that moment, because this will be diminished in proportion as the mental fatigue increases. With the methods of memory, arithmetic, and combination the children are subjected to a mental tension which must certainly influence the experiment. In these cases, perhaps, the children may either be able to accomplish more than their minds are properly capable of at that moment, or, on the other hand, being preoccupied with the task that has been set them, by the effect of a natural inhibition, they cannot do as much as they might have done if they had not had such a preoccupation. Writing from dictation is, however, a task adapted to all the children in a class, and it does not preoccupy them at all because they are in the habit of doing it. It is done only with the help of attention and without the necessity of bringing superior faculties of mind into play. Therefore, according to the greater or less number of mistakes that are found in the written matter, one can infer with certainty the amount of attention that the children are able to give to a subject at a particular time and thus naturally the degree of mental fatigue.

I accordingly chose this last method for use in my study of mental fatigue. I examined 320 boys of the average age of 11 years four months and a half, and 140 girls of the average age of 11 years and eight months. These 460 children were divided into nine different classes, in which, although the plan of instruction during the year was the same, the teacher had certainly an individual influence. For this reason I thought at once that my investigations would not be made under uniform conditions, but I nevertheless tried the experiment. The results that I obtained in the nine classes for the most part presented similar features, and are therefore, I think, of considerable importance. With the help of an intelligent teacher I arranged six passages for dictation, almost equal in respect of the difficulties that they presented and in the number of words. I used each of these six dictations for an experiment. The first was given to the children at 9 A.M.—i.e., at the commencement of school hours; the second at 10 A.M., at the end of the first lesson; the third at 11 A.M., precisely at the end of the second lesson; the fourth at 11 45 A.M, immediately before the luncheon hour and midday rest; the fifth at 12 45 P.M., when school was resumed for the afternoon; and lastly, the sixth at 2 P.M., during the last half-hour of lessons. Each of these dictations was given in the classes in which I experimented on a day selected at random, so that the teacher might not have any influence on the experiment. I took accurate note of the subjects that had occupied the children's minds from the beginning of the lessons till the moment in which they were set to write from dictation.

I collected the material in two months, about 2760 dictations. Each of the experiments was conducted in the following manner. When the children were ready the first sentence was dictated, sometimes by me, but oftener by the teacher in my presence, and repeated by one of the children who usually had this duty. Every one of the children wrote it at once, and that done each put down his pen and raised his head, so that he could not look again at what he had written. The second sentence was dictated when all had finished writing the first. This method was continued until the end, and as soon as all the sentences were dictated the papers on which the children had written were collected at once. The children were told that they were expected to do their dictation *well* and not to hurry themselves. Each dictation took from 20 to 25 minutes For the correction and counting of the mistakes I followed Friedrich's method, reckoning separately mistakes and auto-corrections. I considered as mistakes also the unwritten words and parts of sentences left out and the extra words, as auto-corrections the right letters written over the wrong ones. I counted also the children who did not make any mistakes and divided the others into groups corresponding to the number of mistakes that they had made. The results which I obtained in my trials I have collected in several tables that give an exact idea of the quality of the work done by the children at the end of each hour of lessons. In my treatise on "Mental Fatigue in Children" I have inserted many tables to render comparison easier and the numerous results that I obtained more intelligible, but in the present short article I have given only one table which summarises the results obtained in all the classes as if they were only one, in which there were 460 children of the average age of 11 years and six months.

GENERAL SUMMARY OF RESULTS

Trial.	Hours	Average age	Written Letters	Mistakes		Differences	Auto corrections		Children who did not make mistakes.		Average of the mistakes for every child.	Below the average	
				Total	Per cent		Total.	Per cent.	Total.	Per cent		Total.	Per cent.
1	9¼	11 years and 6 months	117,802	1399	1·187		126	0·106	31	7·69	3·47	222	55·08
2	10		129,808	1205	0·928	−0·259	182	0·140	59	14·04	2·86	232	55·23
3	11		125,030	1165	0·931	+0·003	163	0·130	61	14·28	2·72	245	57·37
4	11¾		127,500	1227	0·962	+0·031	127	0·099	72	16·90	2·88	248	58·16
6	12½		123,900	748	0·603	−0·359	95	0·076	119	29·31	1·84	233	57·38
6	14½		126,793	1614	1·272	+0·669	170	0·134	40	9·63	3·88	256	61·63

From this table it appears (1) that the best result was obtained at 12 30 P M —i e , after the mid day rest; (2) that the worst result was obtained at the end of the afternoon lessons; (3) that the greatest difference in the results between two consecutive experiments occurs on comparing the fifth and sixth trials; (4) that after the work done at the end of the afternoon lessons the next worst in point of quality was that which was done at 9 30 A M —i e , at the time when the children arrived in school in the morning; (5) that comparing the work done after an hour's lesson with that which was done when the children arrived in school in the morning, the first was better than the second; and (6) that the differences between the results of the second, third, and fourth trials were so small that they might be considered as equal When I had finished these experiments I made others with only one dictation, which I gave at different hours in different classes or even in the same class. In the first case the instruction of different teachers certainly had an influence upon the percentage of the mistakes and therefore upon the comparison of the results, and in the second case the same dictation given under the same rules, though on different days, ended by annoying the children, who after some trials worked without any attention I always had the best result at 12 30 P M —i e , immediately after the rest between the morning and the afternoon lessons The worst result I had constantly at 2 30 P M —i e , at the end of the afternoon lessons The proofs that I obtained in these experiments in the morning were very unequal, but, for the reasons that I have given, they did not merit great consideration These experiments, then, confirmed to a great extent the results obtained before

The conclusions I arrived at were the following: (1) I could not draw any conclusion as to the influence of the single subjects of teaching; (2) the first hour of lessons is a useful mental exercise, because the children are able during that time to overcome the state of inattention in which they were at the time of coming to school; (3) the morning lessons do not produce great mental fatigue; (4) the midday rest is of great use to the children because it does not destroy the good effects of the mental exercise in the morning and enables them to do work of better quality than that which they produce after a long rest, as one observes at the beginning of the morning lessons; and (5) though immediately after the midday rest the children are in the best conditions of mind, an hour or so of application in the afternoon is sufficient to produce such a mental fatigue as to lead at the end of the afternoon lesson to the worst work of the day Therefore, if the morning application does not fatigue, it consumes the mental energy of the children in such a manner that they cannot undertake light work in the afternoon without falling into great mental fatigue

Bologna, Italy.

THREE CASES OF MYXŒDEMA OF VARIED TYPE.

By WILLIAM WYLLYS, M R C S Eng , L R C P. Lond , L S A

THE following three cases of myxœdema which have come under my care in general practice during the past seven years were of so varied a character and ran such different courses that a description of them may prove of interest and possibly be of some assistance to the diagnostician Two of the cases in particular demonstrate the difficulty of early diagnosis from the insidious nature of the onset of this disease

CASE 1 —A woman, about 60 years of age, was first seen by my senior partner one night in response to a message on account of very, obstinate constipation combined with a curious alteration in her manner and low state which caused her relatives some alarm I saw her three days later when I made this note: "Pulse weak and slow, eyes puffy, body swollen, headaches, bowels not open, hands stated to feel numb, mind deranged; urine to be tested." I had not made up my mind what was the matter with my patient, though I was partly on the track My father, on seeing her the next day, made this note "Has a myxœdematous look, with slow speech, thickened features, &c ," with which I entirely agreed, and a correct diagnosis having been attained I started by giving the patient five grain tablets of thyroidin three times a day. By this time, however, she had become so unmanageable and suffered from so many delusions and hallucinations that very few tablets were taken. Her power of deglutition, too, was so much involved that she could and would take but very little nourishment Respiration, except during paroxysms of mental excitement, was slow and shallow She became very suspicious at times and at others was extremely dull On one occasion during a bout of mental instability she nailed up all the doors in her house and then stood still in the middle of her room for one and a half hours without speaking, she then broke into a hymn and finally she fell down, though she did not become unconscious Her skin was generally thickened, harsh, and dry and in places it was parchment-like (her hands especially so) and of a deep red tint She was troubled much with flatulence and intractable constipation. There was marked proliferation of the skin about the nose which desquamated freely Six weeks from being first seen she was so wildly maniacal that her removal to the lunatic ward of the workhouse infirmary had to be effected and there she died a few weeks later with acute mania Her family history was of moment, as both her father and her brother had died from "dropsy" and, according to her relatives, were affected much like my patient Her eldest daughter, too, died from "dropsy and mortification," aged 20 years

CASE 2 —A woman, aged 45 years, sent for me one morning at two o'clock on account of an attack of diarrhœa with sickness, which had presumably been caused by her having eaten on the day before sausages, shrimps, and plaice She was down for a holiday at Yarmouth, which may account for this curious dietary. Her pulse was 78 and her temperature was 97° F , her hands and feet were very cold An effervescing mixture with pills of calomel and opium (one quarter of a grain of each) were given and the intestinal symptoms abated, though her exhausted condition caused me some uneasiness Her apathy and disinclination to get up when her condition improved aroused my suspicions, and with a history of "a sensation of closing up in her throat after talking" I thought neurosis was the fault For the next few days her temperature was 98° in the morning and the evening; her pulse ranged between 60 and 68 and was of low tension and volume She complained that for the previous 12 months she had felt easily tired and languid and had repeatedly suffered from aching pains in the legs, and that the skin of her face and hands had assumed a yellow tint She also said that her face had become puffy and that her teeth and her hair had fallen out and also that the skin on her legs had become rough She had suffered from menorrhagia, leucorrhœa, and chronic diarrhœa for some months Her speech was of a measured type and her movements were slow With these symptoms and signs I deemed a diagnosis of myxœdema to be logical, and accordingly I prescribed five grain tabloids of thyroidin, one to be taken every night and morning, with the effect of which she was delighted, stating "that they made her feel much better," and she asked me to write to her usual medical attendant describing them and stating what I considered her complaint to be, so that she could continue with the treatment on her return home I regret to say that the urine was not examined A few days later she had to go home though she still felt very weak, and I soon afterwards received a letter from her medical adviser saying that he quite concurred in the view which I took of the case and that he should proceed with the thyroid treatment The insidious nature of the disease and the very slight alteration in the state of the patient from month to month no doubt made a correct conception of her malady very difficult, especially as I believe that she had never been acutely ill enough to be confined to bed so that a thorough overhaul of her condition might be made; but viewed as it were with fresh eyes and from a new standpoint, after a depressing attack which accentuated her mental apathy and nervo-muscular debility, a diagnosis of her complaint was not so difficult a matter

CASE 3 —A married woman, aged 52 years, the mother of many children, with a history of having been "an ailing woman for two years," was first visited professionally on account of an attack of sickness accompanied by loss of appetite and insomnia Her aspect was "renal," her feet were œdematous, and a faint systolic murmur could be heard at the base of the heart. The urine was acid, and its specific gravity was 1030 It contained no albumin, and urates were present Although the patient was resting in bed on a low diet vomiting persisted, in a few days marked stupor became evident, and the case for a time looked like one of cerebral origin. The urine was again tested with negative results. The patient became very weak, her breath was short, and she was apathetic. Her breath was very foul and her tongue was thickly furred, flabby, and large; the lips were full and livid, the face was decidedly puffy, and the bowels were very costive. Increasing signs of mental failure, loss of memory, stupor and giddiness with melancholia, and falling out of her hair, associated with a bruit about the aorta, pointed to syphilis, and iodide of potassium was tried but without avail. The probability of myxœdema being the *fons et origo mali* next suggested itself and a five-grain tabloid of thyroidin, to be taken twice daily, was prescribed with the result that in three days an obvious change for the better had set in, the patient saying, to use her own words, that "she did not feel so dull." She also began to sleep better, was more inclined for conversation, and she looked decidedly better. The thyroid gland was felt for but could not be made out. The patient for the first few weeks was kept in bed and the dose of thyroidin was gradually increased from two to four tabloids a day and saline aperients were given. This line of treatment was persisted in for six months, the patient, though inclined to shortness of breath and aching of the legs, eventually being able to walk up to my house in very fair health and spirits to see me. Her pulse had become of good volume and tension, the œdema of the feet had disappeared, her face and lips were but very little swollen, and having so far recovered she left off the treatment. A year has passed by and I have just seen her again. Although she is able to perform her household duties, if she is not hurried, she is obviously in need of thyroid tablets, as she has marked dyspnœa, swelling of the ankles, puffiness of the face, and disinclination for much mental effort. The instructive points in this case from a diagnostic standpoint are, I consider, (1) its resemblance to Bright's disease; (2) symptoms which seemed to point to brain disease; and (3) signs of atheroma of the aorta; in reality, however, myxœdema was the cause of her illness. The sloppiness of the conjunctivæ referred to by Chapman[1] as due to the presence of mucin, and diagnostic of myxœdema when no albumin is found in the urine, was well marked when I saw my patient last.

◆

NOTE ON A QUIET EFFUSION INTO THE KNEE-JOINTS.

By J. LIONEL STRETTON, L.R.C.P. LOND., M.R.C.S. ENG.,
SENIOR SURGEON TO THE KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

IN the report of a very interesting lecture on the above subject by Mr. William H. Bennett contained in THE LANCET of Feb. 23rd, p. 527, it is stated that "it is limited to girls and women and is always associated with menstrual irregularity or uterine trouble." As I have met with several cases which appear to be exactly similar to those described save for the fact that they occurred in males, perhaps it may be of interest to mention them. I have only exact notes of the last case which I append.

The patient, a boy, aged 11 years, was brought to the hospital on Oct. 4th complaining of swelling of the right knee which had existed for several weeks. There was no history of injury and his family were all healthy—no tuberculous or syphilitic mischief. He walked into the consulting-room without difficulty and did not complain of pain. On examination the right knee was found to be swollen and contained a considerable amount of fluid. When standing the gravitation of the fluid to the lower anterior part of the joint was well marked. On comparing it with the other knee effusion was found in that also but not so much in amount. The circumference of the right knee was 13½ inches and that of the left 12 inches. There had been no injury and nothing could be elicited to account for the condition. There was no increase of temperature or other constitutional trouble. He was put to bed and the knees were kept on back splints with lead lotion, &c. He was blistered, treated with Scott's dressings and plaster-of-Paris cases. Internally he was given a course of iodide of potassium, sodium salicylate, and tonics, but all to no avail, as after two months his condition remained unaltered. He was put in plaster-of-Paris cases and allowed to get up and walk about. He went home and when he reported himself a month later the effusion had very much diminished. He was ordered to have his limbs and knees massaged and to leave off the cases. When seen a few days ago, six months since his admission, the effusion had entirely disappeared and he was able to walk about without causing any swelling.

Kidderminster.

NOTES ON TWO SUCCESSFUL CASES OF OVARIOTOMY WITH COMPLICATIONS, ILLUSTRATING THE VALUE OF SALINE FLUSHING.

By E. J. TREVOR JONES, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE ABERDARE COTTAGE HOSPITAL.

CASE 1.—The patient, a married woman, aged 32 years, consulted her medical attendant nine months after marriage because she was alarmed at the rapidly increasing size of her abdomen—a condition which was at first thought to be pregnancy. I saw her in consultation with Mr. F. Finney and an ovarian cyst was diagnosed. She was admitted to the Aberdare Cottage Hospital in June, 1900. On opening the abdomen the cyst was found to be unusually tense and large, with many adhesions. On introducing the trocar the tense cyst ruptured and in spite of careful packing much of the contents escaped into the peritoneal cavity. After emptying the cyst the adhesions, which were unusually numerous in a cyst only seven months old, were ligatured, but the omentum was found to be adherent to the intestine. The adhesions were dissected off and part of the omentum was ligatured and taken away. The abdomen was then thoroughly irrigated with warm saline solution (one and a half drachms of chloride of sodium to the pint of sterilised water). When the fluid had returned clear the abdomen was united with silkworm-gut sutures through *all* the coats. The cavity was left filled with the saline solution and the wound was dressed in the usual way, but without drainage. A slight rise of temperature occurred on the first and second nights, after which the patient made a good recovery.

CASE 2.—The patient, aged 66 years, unmarried, had since the climacteric noticed a gradually increasing tumour of the abdomen which was diagnosed as an ovarian cyst. The operation took place in the patient's home on August 12th, 1899. A three-inch incision was made and the trocar was introduced in the ordinary way. On emptying the cyst by pressure it ruptured and some of the contents escaped into the peritoneal cavity. In this case the adhesions were few and the wall of the cyst seemed to be undergoing degenerative changes. On introducing the hand to ligature the pedicle a moderately-sized tumour was detected which on examination proved to be a uterine fibroid. The abdominal cavity was thoroughly irrigated with the sterilised saline solution and the abdomen was treated as in the previous case, leaving the cavity of the peritoneum filled with the solution. The patient made an uninterrupted recovery and has since enjoyed good health.

I have thought it worth while to put on record my experience of the value of irrigation with saline solution and the retention of the solution in the abdomen. The solution seems to me to act by absorbing any septic matter that may remain in the peritoneal cavity. I also noticed that these two patients suffered very little from thirst after the operation, which fact may be accounted for by the absorption of fluid from the abdomen.

Aberdare.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.

A SUCCESSFUL CASE OF SUPRAPUBIC LITHOTOMY IN A CHILD.

(Under the care of Mr. EDGAR HUNTLEY.)

WE have within the last few years published no small number of cases in which the suprapubic operation for the removal of a vesical calculus has been performed with success, and, indeed, in the hands of a general surgeon the results are as satisfactory as those following any other method. For those who have had special opportunities of performing lithotrity that operation is doubtlessly to be preferred, not merely for the small mortality following its employment, but also for the rapid convalescence which ensues. It may, indeed, be said that the crushing operation is more likely to be followed by a recurrence, but the modern improved methods make it very improbable that any particle of the original calculus will be left behind, and even should it happen that a fresh calculus forms its removal is certainly less troublesome than a second lithotomy.

A boy, aged six years, the seventh child of healthy parents, was taken to the out-patient department of St. John's Hospital, Lewisham, early in December, 1900, when the following history was obtained. Until two years before, although considered delicate, nothing definite seems to have ailed him. He was suckled till he was 11 months old and then he partook of the fare of the parents. About two years ago he had been taken to the Miller Hospital, Greenwich, for painful micturition and inability to pass urine freely. He was there circumcised, the operation resulting in only partial benefit, for he does not seem to have lost either the pain or difficulty in passing urine for any length of time together. These symptoms, however, were not very marked until June, 1900, when he developed measles. Both the pain and difficulty then increased and remained so until his admission to St. John's Hospital on Jan. 1st, 1901. The history obtainable during the months from June to December, 1900, was that the pain and difficulty were not noticed from day to day, the child on occasions going two or three days without any trouble at all, then he would have them return many times in one day, passing small quantities of urine at a time, the pain not occurring at any special period of micturition and no blood ever coming away.

On Jan. 1st, 1901, the patient was admitted under the care of Mr. Lennard Stokes, to whom Mr. Huntley is indebted for permission to publish these notes. The case was handed over to Mr. Huntley during Mr. Stokes's temporary absence. The child was at first allowed to run about and was simply watched to ascertain definitely whether the above symptoms occurred. For 10 days pain on passing urine only happened once, but every night, and three or four times in a night, he wetted the bed in his sleep. On the 11th he was given A.C.E. mixture and his bladder was sounded. A stone was at once struck. A little delay occurred before the operation could take place, as the child developed a cough which had to be got rid of. From then until Feb. 11th there were several attacks of pain on micturition and the bed-wetting occurred nightly. The urine never contained any blood, was of specific gravity 1020–1025, was acid, and only on one occasion contained any albumin

On Feb. 11th the patient was again given A.C.E. mixture and the bladder was washed out with warm boric lotion through a catheter. The lotion all being drawn off, four ounces of boric lotion were gently thrown into the bladder by means of a brass syringe. The catheter (No. 5) was allowed to remain in, an indiarubber band being tied round the penis and the end of the catheter blocked with a wooden match. No rectal bag was used. The abdomen having previously been thoroughly cleansed was given a final wash, and an incision about 2½ inches long was made in the middle line ending immediately above the symphysis pubis. There being a few vessels bleeding these were twisted off and the linea alba was divided to the same extent as the skin incision. After dividing the underlying soft structures and picking up a few veins the bladder wall was reached. Before opening this two long threads of horsehair were passed into the substance of the bladder wall, one towards the upper end of the exposed part and the other at the lower end. These were tied and the long ends being gently pulled forwards brought the bladder well up into the incision. The bladder was now opened with the knife between the two threads. As soon as some of the lotion had escaped, a pair of ordinary dressing forceps was passed in and the stone was brought to the surface. The stone being too large to come through the incision in the bladder this had to be enlarged upwards before extraction. The match in the catheter was then removed and the urine-stained lotion was allowed to run out. The two horsehair threads were still held up while nine Lembert's sutures of horsehair were passed by a fine curved needle. These were placed very close together and their ends were cut quite short. The long threads were then removed and the bladder was allowed to drop back. After all had been made dry the soft structures were brought together with silk and the skin was sutured with a continuous stitch of horsehair. The wound was dressed with iodoform gauze. The rubber band being removed the catheter was tied in, rubber tubing draining the bladder under the bed.

For two days the patient had rather severe vomiting, but after this he took plenty of milk food. On the third day after the operation urine was noticed to be coming along the sides of the catheter, but this was not removed until the fifth day. After this there was no trouble except for the coming away of one of the abdominal stitches. The patient left the hospital on March 12th, 1901, perfectly well. The size and weight of the stone were as follows: length, 17 millimetres (⅔ inch); breadth, 13 millimetres (½ inch); and weight, 1·5 grammes (23 grains)

ROYAL SOUTHERN HOSPITAL AND STANLEY HOSPITAL, LIVERPOOL.

FOUR CASES IN WHICH THE MURPHY BUTTON WAS USED—IN THREE SUCCESSFULLY.

(Under the care of Mr. G. P. NEWBOLT.)

IN the first of the following four cases an irreducible intussusception had to be dealt with. Resection of the irreducible portion is probably the best treatment if the anastomosis can be effected quickly, though the cases in which recovery follows in children are very few indeed as the increased shock of the resection is generally fatal. Of the four other methods of treatment which are possible for this condition[1] it cannot be said that any other offers a better chance of recovery, though the establishment of an artificial anus above the invagination is very simple. The death in Mr. Newbolt's case cannot be attributed to Murphy's button. The success of the button in the three other cases is a proof that in suitable cases and with the exercise of care very satisfactory results may be obtained with it The Lembert stitches in addition are not usually necessary, but if time be available their application does no harm. The great bulk of the button is decidedly an argument against its use for intestinal anastomosis in femoral hernia where the bowel has to be returned through a small opening

CASE 1.—A boy, aged four years, was admitted into the Stanley Hospital, Liverpool, under the care of Mr. Newbolt, on Jan. 7th, 1898, suffering from an intussusception. He had been ill for two weeks and was very much collapsed; his pulse was 110, his abdomen was distended, and he was under the influence of opium. The intussusceptum could be felt both per rectum and through the abdominal wall. He had vomited for several days and had passed blood and mucus per anum. Mr Newbolt opened the abdomen in the middle line, but was unable to get at the tumour without turning out some of the distended intestines. Being unable to reduce the last portion Mr. Newbolt resected the gut and put in a button. He had, however, to open and to evacuate the distended intestines before he could return them into the abdomen. The patient rallied at first from the operation but died 12 hours later. An examination of the resected intestine showed that the approximation was perfectly good, but the button had no trial.

---

[1] G. L. Kerr Pringle Bristol Medico-Chirurgical Journal, December, 1899.

Case 2.—A widow, aged 70 years, was admitted into the Royal Southern Hospital on May 15th, 1900, suffering from a strangulated femoral hernia on the left side. She was an old woman of spare habit and had been taken ill on May 12th with vomiting and pain in the abdomen; no motion and no flatus had been passed for three days. To her knowledge she had had no rupture before, but she had been working hard previously. On examination there was a tense globular swelling, both tender and painful, in the left femoral region. The abdomen was slightly distended. The pulse was 94, small and irregular, the respirations were 24, and there was a trace of albumin in the urine. Altogether the case did not look a very favourable one. Mr. Newbolt cut down on the swelling and on opening the sac exposed a piece of black, dull-looking, and œdematous gut. The stricture which was very tight was next divided and the bowel was drawn down until a healthy part was exposed. The wound being packed off with gauze an assistant held the bowel on each side of the gangrenous portion with his fingers whilst Mr. Newbolt removed the damaged piece of gut; there was very little bleeding from the divided parts, as hardly any mesentery was removed. The button was now inserted in the usual way and the two ends of intestine were brought together. Some Lembert's sutures were passed after drawing together the ends of the bowel so as to take tension off the button. After irrigating the parts the bowel was returned into the abdomen, but before doing this the ring had to be enlarged. The sac was next removed, the stump was tied up to Poupart's ligament, and the wound was closed. The after-progress of the case was quite satisfactory. The patient was kept on water, brandy, and beef-tea for a week; her bowels acted on the seventh day after an enema; and the button was passed on the eighteenth day. There was slight suppuration in the external wound. The patient went home seven weeks after her admission and is at present working and looking after five lodgers.

Case 3.—A man, aged 49 years, a cotton porter, was admitted into the Royal Southern Hospital under the care of Dr. William Williams. The patient had been ill for about eight months before admission and complained of constant vomiting, of wasting, and of pain in the abdomen. He was a spare-looking man and was much wasted. There were large veins over the abdomen and a doubtful mass could be felt in the region of the pylorus. On May 22nd, 1900, the patient being under chloroform, Mr. Newbolt opened the abdomen in the middle line midway between the ensiform cartilage and the umbilicus. The stomach presented and the pylorus was seen to be involved in a large mass about three inches long. The glands were enlarged both in front and behind the growth. The stomach was pulled partly out of the wound and avoiding the colon a piece of jejunum was brought up to the stomach and held in position. An incision having been made into the stomach one half of the button was inserted and a suture was run around it; a similar proceeding was carried out with the intestine, the two halves of the button were brought together, and a few sutures were inserted to make all secure. The stomach and intestines were then returned to the abdomen and the wound was closed. An inch button was used. The patient made an excellent recovery and never vomited after the operation. In a short time he was able to take solid food but he could not digest potatoes or meat without discomfort. He, however, put on flesh and though he had some lumbar pain and flatulence at first he eventually became very comfortable and considered himself well. The button was never seen and it was thought that it had not been passed. He died some seven months after the operation, but simply from the progressive disease. The anastomosis relieved his vomiting and enabled him to take food until shortly before his death.

Case 4.—A stableman, aged 41 years, was admitted into the Royal Southern Hospital on Sept. 18th, 1900, suffering from a strangulated femoral hernia on the left side. He had had a lump in the left groin for six years and this had gradually increased in size, but was easily reducible until two months before when it came down and was only reduced with the greatest difficulty. At 10 A.M. on the morning of admission whilst working in the stable the lump came down bigger than ever and he began to vomit. On examination at 4 P.M. there was a hard tense swelling of the size of an egg in the left femoral region and the patient was vomiting brown fluid, not stercoraceous. Mr. Newbolt cut down and opened a sac containing a large mass of doubtful-looking omentum and a piece of small intestine, the stricture was divided, the omentum was drawn down and removed, and the damaged portion of gut was then examined. It was shiny but very black and did not bleed when incised superficially. In spite of the stricture being freely divided there was no evidence of any circulation going on in the damaged gut. Mr. Newbolt therefore excised it as in Case 2, with the exception that he removed a V-shaped piece of mesentery and for his trouble got a good deal of bleeding from the cut edges. The button was put in, the gut being held by the fingers of an assistant, and no clamps were used. The opening into the abdomen again had to be enlarged before the gut and button could be returned. The sac was removed and the wound was closed as in the other case. The patient made a perfect recovery; he passed flatus on the next day and his bowels acted on the eighth day after an enema. On the twenty-third day after an aperient he experienced pain in the rectum and on examination the button was detected, of which after a glycerine enema he was safely delivered on the twenty-fourth day after operation. There was slight suppuration also in the external wound as in the other case. The patient remains quite well.

Remarks by Mr. Newbolt.—During the last three years I have used the Murphy button in four cases. In three of these the result was all that could be desired, while in the fourth case the patient died so soon after the operation that the button had no trial. So far, therefore, my limited experience is in favour of the button, for these cases comprise the only instances in which I have used the appliance. In Case 1 and Case 2, in which I was anxious to get my patients off the table, I was able to operate fairly quickly by means of it. In each instance I used Lembert's sutures over the button, though this is not held to be necessary, but it only takes a few minutes and by so doing a good deal of strain is taken off that portion of the intestine which is gripped by the button and there can hardly be a leakage. I believe that the fingers of an assistant are far better than any clamp if available. I think that damage is done by clamps. In both cases of hernia I had to enlarge the ring pretty freely in order to reduce the gut containing the button; this is a drawback, as it weakens the parts afterwards. I do not think it is likely that any patient will get rid of the button without knowing it. There was a good deal of discomfort and pain in both of my cases in which it passed. In Case 3 I presume that the button fell back into the stomach, though an x-ray photograph did not show it. In the Transactions of the Clinical Society for 1900 Mr. J. Hutchinson, jun., tabulates cases of Gangrenous Intestine in Hernia treated by Enterectomy with Murphy's button, and quotes 14 cases with one recovery, but this does not give, I think, anything like the ordinary percentage of recoveries. Taking the Royal Southern Hospital alone there have been five enterectomies done with the button, and of these four recovered—i.e., the two which I publish and two by the late Dr. H. G. Rawdon.[2] The notes of these four cases were read before the Liverpool Medical Institution.

The Medical Golf Tournament.—The medical golf tournament bids fair to become an annual institution. The tournament for 1901 will be played on June 6th on the links of the Mid-Surrey Club, Richmond, which have been lent for that day by the club. Competitors will be divided as last year into two classes and there will be a prize for each class. Play will be 18 holes *v.* bogey, with a foursome sweepstake in the afternoon. There will be also a prize for the best last nine holes *v.* bogey in each class. Entries, stating lowest handicap and enclosing 5*s.*, to be made on or before June 5th, to the honorary secretary, Mr. Rolf Creasy, Windlesham, Surrey. It is proposed to hold a dinner in London on the same evening if a sufficient number of gentlemen promise to attend; tickets 7*s.* 6*d.*, exclusive of wine.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

[illegible] Meeting.

[illegible] held on May 7th in the I[illegible] Hospital, Mr. W. WATSON C[illegible] he chair.

Mr. W. C. C. PAKES demonstrated the apparatus which he had used for the Collection of the Gases produced by Bacteria. The gases were collected by the displacement of mercury, instead of over water or brine. He also showed a method of inoculating large flasks under strictly anaerobic conditions. He had found that the bacillus pyocyaneus and some other organisms which were generally regarded as anaerobic would grow aerobically when the culture medium contained nitrates.

Mr. PAKES also made a communication upon the Effects of Media containing high percentage (4 or 5 per cent.) of Nitrate upon the Morphological appearances of certain Bacteria. The bacillus pyocyaneus appeared like a cladothrix and the bacillus typhi almost like a blastomyces.

Dr. F. F. CAIGER, Dr. R. M. BEATON, and Mr. PAKES made a communication on the Value of Neisser's Stain in the Diagnosis of Diphtheria. They gave an account of 100 cases which had been admitted to the South-west Fever Hospital certified as suffering from diphtheria. These cases were diagnosed both clinically and bacteriologically, the former at the Fever Hospital and the latter in the laboratory at Guy's Hospital. The results showed that the two diagnoses agreed in 70 per cent. In 25 per cent. of the cases in which diphtheria was diagnosed clinically the bacteriological examination failed to show bacilli upon culture. In 5 per cent. the bacteriological examination showed the Klebs-Löffler bacilli when the clinical evidence was negative. They concluded generally that Neisser's stain made the bacteriological examination more easy than when only methylene blue was used. The disease could by this means be [illegible] ortion of cases from the examinati[illegible] directly from the swab by the us[illegible] account of the more distinctive [illegible] bacilli after staining by Neisse[illegible] of the disease bacteriologically could be made by those who could not be regarded as experts. It was a fact of great value that the bacillus could be revealed by the direct examination, without loss of time, of a cover-slip made from the throat swabs. In 18 out of 48 cases they had been able to accomplish this operation, which required, however, some manipulative and practical experience.

Dr. J. A. BUTLER and Dr. H. S. FRENCH gave a preliminary account of a Research upon the Nitrogenous Metabolism in Bright's Disease. The investigation had been carried out during a period of 41 days upon a boy, seven years of age, suffering from subacute nephritis. During the last 12 days of the period he had mild but distinct symptoms of uræmia. The estimations made were: (1) the total nitrogen in his daily intake; (2) the total nitrogen in his daily output of urine; (3) the nitrogen excreted as urea in his urine; (4) the nitrogen excreted as coagulable proteid in his urine; (5) the nitrogen excreted as uric acid in his urine; (6) the total nitrogen in his fæces; and (7) the nitrogen as "other bodies" in his urine. The conclusions arrived at were as follows: (1) that when the patient was most ill he was excreting more nitrogen than when he first came into hospital, whilst when he was better the urine and fæces together did not return as much nitrogen as his food contained; (2) that the relation of the nitrogen as urea in the urine to the total nitrogen in the urine was less than during health—namely, 75 6 per cent. instead of 86 per cent.; but that if the nitrogen present as coagulable proteid were first deducted from the total nitrogen in the urine then the nitrogen as urea formed 83·4 per cent of the remainder; (3) that the relation between uric acid and urea was as 1 to 47 6, which was not very different from the proportions found during health by many observers, though less than the figure given by Haig as normal—namely, 1 to 35; and (4) that the amount of nitrogen in the fæces was relatively large—namely, 14·7 of the total in urine and fæces—whereas other observers had found, some 6 and others 11 per cent.

Mr. J. W. EYRE made a communication on the Differential Diagnosis of Strains of Pneumococci. In a previous communication by Dr. J. W. Washbourn and himself it had been pointed out that there exist varieties of the pneumococcus which at present could only be distinguished by the action of anti-pneumococcic serum. Out of six strains of pneumococci under observation at that time, which appeared identical in respect to their morphology and cultural reactions, Pane's anti-pneumococcic serum would protect against five but not against the sixth. The results of some previous observations on the reaction of various nutrient media and the method then adopted to obtain a standard reaction[1] were then described. Phenolphthalein was used as the indicator and the reaction thus estimated was shortly expressed by stating the number of cubic centimetres of normal acid or alkali required to exactly neutralise one litre of medium, the signs + and – being prefixed to indicate acidity or alkalinity respectively. It was also suggested, provisionally, that media having a reaction of +10 should be used as a standard for general work. In the course of some experiments to determine the "optimum reaction" for the growth of two special strains of the pneumococcus Mr. Eyre found that there was a constant optimum reaction for each. The two varieties of cocci employed were those numbered 1 and 5 in the paper previously referred to, and differed in that animals experimentally inoculated could be completely protected against strain No. 1 by the use of anti-pneumococcic serum, but the serum was powerless to protect rabbits inoculated with strain No. 5. Whilst No 5 preferred medium having a reaction of +10, No. 1 selected +8. So marked was the preference of each of these two varieties of cocci for its respective "optimum reaction" that cultivations made in such media would give evidence of growth, macroscopically, in from five to six hours (at a temperature of 37° C.), whilst cultures in media of other reactions did not show sufficient growth to be visible to the naked eye under 10 or 12 hours. Broth cultivations of the two strains of pneumococci six hours old were exhibited.

Dr. J. H. BRYANT reported the Bacteriological Examinations of three cases of Ante-mortem Thrombi. In the first case, which was one of mitral stenosis and tricuspid regurgitation, extensive ante-mortem thrombosis of the pulmonary arteries was found at the post-mortem examination made five hours after death. Streptococci and the staphylococcus albus were found in cultures and microscopical preparations. In the second, which was a case of tuberculous peritonitis with thrombosis of the right lateral saphenous vein, a pure culture of the proteus vulgaris was obtained, the post-mortem examination, however, being made 20 hours after death. In the third, which was a case of diffuse carcinoma of the stomach with thrombosis of both saphenous veins, a pure culture of bacillus subtilis was obtained from the left saphenous vein and of staphylococcus albus from the right saphenous vein. The post-mortem examination had been made four hours after death. The relation of these bacilli to the thrombosis was discussed. The finding of non-pathogenic organisms like proteus vulgaris and bacillus subtilis was particularly interesting. The latter had possibly found its way into the blood-current through an old ulcer which the patient had on his leg.

Professor VAUGHAN HARLEY and Dr. WAKELIN BARRATT gave a demonstration of the Production of Hepatic Cirrhosis by Ligature of a Single Bile Duct. The change thus produced was limited to the area of the liver drained by the ligatured duct, and the rest of the liver remained unaffected. The general health of the animals operated upon was in no way altered. The change produced resembled that present in the human liver in cases of cirrhosis. There was an interlobular growth of fibrous tissue containing numerous bile-ducts of new formation The hepatic lobules underwent atrophy and might entirely disappear. The largest bile-ducts were dilated and tortuous, but still contained bile even as long as 16 months after ligature. The subject was illustrated by lantern slides.

Dr. R. H. J. SWAN exhibited a specimen of Calcified Hydatids taken from the body of a man, aged 66 years, which had been discovered accidentally in the dissecting room. The patient had been admitted with bronchitis the day before death and no clinical history was obtainable.

Mr. J. H. TARGETT exhibited microscopic specimens from a case of Cirrhosis of the Liver.

OBSTETRICAL SOCIETY OF LONDON.

Adjourned Discussion on the Pathology and Treatment of Puerperal Eclampsia, with Special Reference to Treatment by Saline Infusion.—Exhibition of Specimens.

A meeting of this society was held on May 1st, Dr. **Peter Horrocks**, the President, being in the chair.

The discussion on Dr. Hey Groves's paper on the Pathology and Treatment of Puerperal Eclampsia, with Special Reference to Treatment by Saline Infusion, was resumed by Dr. **T. W. Eden**, who said that one of the points upon which all observers were agreed was that albuminuria was attended by a heavy fœtal mortality, from 30 to 77 per cent., and that the fœtus was imperfectly developed. It was important to note in this connexion that a diseased condition of the placenta was also frequently met with in albuminuria, and it seemed probable that this condition had much to do with the fœtal mortality and the feeble development. Without entering into detail, the placental changes might be said to consist of extensive infarction, which had been termed "pathological infarction" to distinguish it from the normal process in the adult placenta. Infarction in the healthy placenta had been shown to start in obliteration of the fœtal arteries; in "pathological infarction" arterial obliteration attained a greater degree of severity. The primary lesion was probably identical in the two. The toxæmic theory of the causation of albuminuria offered the best explanation of the clinical phenomenon of this disease and also of the occurrence of these placental lesions. The accumulation of toxins in the maternal blood would rapidly affect the quality of the fœtal blood and the changes in the fœtal arteries would then be due to the impurity of the blood flowing through them. The toxins might be formed in the maternal tissues, but there was something to be said for the alternative view that they were products of fœtal tissue metabolism. If the toxæmic theory of albuminuria was accepted the renal and hepatic changes must be regarded as mere incidents of the disease and not as the cause of it. The great objection to this theory appeared to him to be that it proved too much, for it would prove that every pregnant woman must suffer from albuminuria. There must in the first place be a deficiency in the normal rate of elimination, allowing of the accumulation of toxins in the blood and thus starting the whole train of symptoms. Sir Andrew Clark had described a condition of "renal inadequacy," due, not to definite changes in the kidneys, but to deficient elimination through those organs. It was possible that some such condition occurring during pregnancy was the primary fault on the part of the mother.

Dr. **Arthur Giles** said that in order to form a clear judgment as to the value of saline transfusion or any other therapeutic measure in the treatment of eclampsia it was necessary to make some further differentiation than was involved in speaking simply of eclampsia. It was necessary, in the first place, to distinguish between renal disease accidently complicating pregnancy and cases of albuminuria with toxæmia due directly to the pregnancy itself. In the second place, a distinction should be made between a condition of diminished or suppressed excretion and a toxic condition of the blood independent of such diminution or suppression. Primary renal disease was generally associated with imperfect elimination, and in such cases the value of saline injections was doubtful. Here it was preferable to rely on the measures applicable to cases of uræmia apart from pregnancy—viz., hot packs, diuretics, and free purgation. On the other hand, the toxis of pregnancy was not necessarily associated with faulty elimination, and in these cases the best results might be expected from the treatment advocated by Dr. Groves. There was a considerable difference in the prognosis also. In the case of primary renal disease the immediate prognosis was worse and there was little prospect of cure after delivery, whilst in the toxis of pregnancy the immediate prognosis was better, recovery after delivery was generally complete, and a repetition of pregnancy was not necessarily accompanied by a return of the symptoms. When saline injection was indicated some authors advocated that it should be combined with venesection in plethoric patients, and it appeared to him that there was a good deal to be said in favour of this plan. The injection of saline solution into the cellular tissue, under the breast or into the abdominal wall, was often easier and quicker than venous transfusion. It had also been said that it was more efficacious inasmuch as the fluid became mixed with the serum in the tissues before passing into the general circulation.

Dr. **Robert Jardine** (Glasgow) said that he believed in the toxæmic theory of eclampsia. The toxin seemed to him to be a waste product of tissue metabolism. Dr. Eden had referred to the belief that on the death of the fœtus albumin lessened or disappeared. He (Dr. Jardine) had seen three severe cases of eclampsia with macerated fœtuses in which the albumin had been abundant. A very important point was how the maternal system dealt with the waste-products. In the first place, elimination by the alimentary canal was below the normal Constipation was the rule in pregnancy and it was markedly so in eclampsia. He believed the toxin acted on the kidneys like turpentine and cantharadine Albumin and often blood appeared, excretion was lessened, and there might be complete suppression of urine. He had brought with him sections from four livers, showing marked evidence of degenerative changes in the cells. He was convinced that the liver played an important part in the destruction of the toxin. He had published a case in which a second attack of profound coma had supervened on the fifth day in which the urine was heavily loaded with bile pigment. The kidneys had been acting very freely or otherwise the patient would probably have died. Dr. Groves believed that increased coagulability of the blood caused multiple thrombosis and thus brought about the fits. He believed that the fits were caused by the toxin acting directly on the nerve centres. The toxin seemed to him to affect the fœtus as it did the mother. He had found albumin in the urine in all cases examined. He had also found it in the urine of several infants whose mothers had had severe albuminuria without fits. Given a toxin in the system he thought the most rational form of treatment was one which aimed at clearing it out through the natural channels by acting on the bowels, the skin, and the kidneys. Diuretics by the mouth were too slow, but by giving a solution such as he used—viz., the normal saline solution with one drachm of acetate of soda to each pint—he claimed that diuresis was quickly established. By the second day diuresis was profuse, the poison was diluted, and the whole system was stimulated. To test the results of this method of treatment he gave statistics from the Glasgow Maternity Hospital. Dr. Munro Kerr had found that during the last 15 years 80 cases had been treated. The old methods had given a death-rate of 47 per cent. while with the saline infusions there was a death-rate of 24 per cent—a fall of very nearly 50 per cent. It must be borne in mind that they had to deal with very bad cases, many of them actually moribund. He personally had had three deaths in 22 cases. He had great faith in the saline infusion as a remedy.

Dr. **Munro Kerr** (Glasgow) said that he was much in favour of the employment of saline infusion in eclampsia. Saline infusion was undoubtedly a most powerful though slow diuretic. In addition to having a diuretic effect the infusion acted as a cardiac stimulant and diluent to the poison. He quoted cases to illustrate these latter two effects of saline infusion. His position regarding saline infusion was that he considered it a most valuable adjunct to the general treatment of the disease. He did not advocate it to the exclusion of such drugs as morphia or chloral, which should be used only if there was much restlessness and the fits were not at once arrested by saline infusion. As regards the high fœtal and infantile mortality he thought that while occasionally deaths might be caused by changes in the placenta such as Dr. Eden had described it was most likely to be due to the same toxins. He mentioned a case that had been under his care in hospital a few days ago where the child of an eclamptic woman was born apparently strong, but had developed on the second day convulsions which were followed by coma and death. The infant's urine contained a large quantity of albumin.

Dr. **Amand Routh** took exception to Dr. Groves's explanation of the way in which the convulsions were brought about—namely, that "the actual convulsions and coma resulted when these toxins caused the coagulation of the blood and the multiple capillary thrombi." He agreed with Dr. Herman that this point had not been proved. As a rule, saline transfusion had not been used till the fits came on, but if it were given in the pre-eclamptic stage the effect on the urine would prove a better test of its utility. They had heard the mortality statistics at the Glasgow Maternity

Hospital before and after this method of treatment, but they were not told what treatment had been in vogue previously to the introduction of the method of saline transfusion. In Dr. Jardine's and in Dr. Groves's cases the saline treatment was not used alone, but was supplemented by the administration of salts, hot packs, veratrum viride, &c. Whatever might be the value of saline transfusion in the pre-eclamptic stage it seemed to him that they would still have to rely on sedatives in the treatment of the actual eclamptic convulsions.

Dr. M. HANDFIELD-JONES thought that it was unscientific to talk generally of treating puerperal eclampsia by saline infusions, as if all cases of this complication were of the same nature and required the same treatment. It was quite true that the retention of toxic products in the system probably often accounted for the convulsions, but in other cases the fits seemed to be originated in the central nervous system. Undoubtedly, in certain as yet undemonstrated cases the injection of saline fluid was useful. Numbers of cases were cured by a single blood-letting, by the evacuation of the liquor amnii, or by the use of sedatives, and in such cases the transfusion treatment was absolutely unnecessary.

Dr. W. S. A. GRIFFITH quoted statistics from Queen Charlotte's Hospital to illustrate his remarks at the previous meeting. From January, 1899, to March, 1901, 2630 women had been delivered, and of these 135 (5 per cent.) had albuminuria, being 7 2 per cent. in primiparæ and 1 6 per cent. in multiparæ. Of these albuminuric cases six patients had eclampsia and they all recovered.

Mr. E. RUMLEY DAWSON disapproved of Dr. Japp Sinclair's statement that no general practitioner should miss the fact that a patient was suffering from uræmia. He (Mr. Dawson) thought that repeated urine testings were impracticable in a busy general practice. He had no personal experience of the treatment by saline infusion, but he thought that the difficulty and occasional danger of the operation should not prevent its being used by general practitioners.

The PRESIDENT said that he was not convinced by the cases published that in saline transfusion they had a remedy for puerperal eclampsia. As a fact there were already many remedies or modes of treatment, and whenever a disease or illness had several methods of treatment it generally meant that there was no known cure. Although pilocarpine was a dangerous drug in unsuitable cases, he believed that, judiciously used, it was a valuable mode of treatment in puerperal eclampsia. With regard to the injection of saline fluid he thought it was perhaps better not to inject it into the veins but into the cellular tissue and rectum, because it must be remembered that in these cases there had been no loss of blood and hence there was no underfilling of the vascular system as in cases of profound hæmorrhage, and moreover the blood-pressure was generally raised owing to the convulsions, and therefore it might not be without danger to add rapidly several pints of fluid. He did not for a moment believe that the blood would absorb the saline fluid from the cellular tissues or from the rectum to any dangerous extent, because it was a physical process (osmosis, &c.) and the blood would cease to absorb any more when the vessels were full. Nevertheless he could not help thinking that if there was any truth in the theory that puerperal eclampsia was due to a toxin circulating in the blood, and any truth in the theory that diluting the blood would cure or mitigate the fits, then blood should be drawn from one median basilic vein and saline fluid should be injected into the opposite one. Or at all events blood should be withdrawn from a vein and saline fluid should be injected into the cellular tissues and the rectum whence it would be rapidly absorbed and so restore the blood-pressure and at the same time dilute the blood. He considered that sufficient evidence had been brought forward by Dr. Groves, Dr. Jardine, Dr. Munro Kerr, and others to warrant further trial of this method of treatment in puerperal eclampsia.

Dr. GROVES, in his reply, dealt with the statistics of mortality of Veit's treatment of eclampsia by morphia and Charpentier's by chloral, but he said that other observers had not met with equal success. He thought that the minute hæmorrhages found in the brain, in the kidneys, in the liver, and in other organs surrounded by areas of necrosis were due to the morbid state of the blood and blood-vessels and not to the mechanical results of the fits. He advocated repeated saline transfusion when there were profound coma, cyanosis, and anuria, with chloroform during delivery.

The following specimens were shown:—

Dr. JARDINE: Microscopical Sections from a Liver in a case of Fatal Eclampsia

Dr. MUNRO KERR: Dermoid Cyst of the Ovary successfully removed during Labour.

Mr. C. E JENNINGS: Transfusion Apparatus.

Lieutenant-Colonel A. J. STURMER, I.M.S.: Perivagina Tumour containing (?) "Hydatidiform" Cysts (referred to sub committee).

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases, Specimens, &c.

A CLINICAL evening of this society was held on May 2nd, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Mr. NETTLESHIP (for Dr. D. J. WOOD) read notes of a case of Pulsating Double Exophthalmos following injury to the head, cured by Ligature of the Left Common Carotid. The patient fell on his head from a bicycle and was picked up unconscious. The exophthalmos developed gradually, pulsation being very obvious, and the left carotid was ligatured 10 days after the accident. Pulsation was arrested immediately, but some signs of aphasia and paresis supervened which cleared up, marked improvement occurring after 24 hours. After operation vision in the right eye was $\frac{6}{6}$ and in the left it was $\frac{1}{60}$ owing to atrophy and scotoma. Pulsation and proptosis were permanently abolished.—Mr. TREACHER COLLINS referred to a case under his care two years ago resulting from a bullet wound. The missile was located by the x rays at the base of the basilar process; there was pulsating exophthalmos and the bruit was not only audible to the patient but to those near him; manual pressure was tried but it proved unsuccessful and Mr. T. H. Openshaw ligatured the common carotid with great benefit, though the condition recurred after eight months in less degree.

Mr. G. W. ROLL exhibited two cases of Congenital Ptosis in which Hess's operation had been performed with benefit. The elder lad had been operated upon three years ago and the cure was probably permanent. One year only had elapsed in the case of the younger, but in this the condition was bilateral and he had quite lost the habit of throwing the head back, common in these cases. Mr. Roll referred to Mr. J. B. Lawford's account of Hess's operation in the thirteenth volume of the *Ophthalmic Review*, but said that he preferred to leave the stitches in 14 days instead of 10 days and also inserted them nearer the free margin of the lid instead of midway between that level and the margin of the orbit.—The PRESIDENT cited five cases in which he had operated, of which two were permanently successful and three appeared to be drifting back to their original condition.

Mr. SIMEON SNELL exhibited a Sarcoma of the Right Orbit removed from a miner, aged 38 years, on Dec. 10th, 1900. A small nodule had been noticed eight months previously beneath the lower lid and had gradually enlarged till at the time of the operation the growth was of the size of a pigeon's egg, freely moveable, painless, and could be pushed back along the floor of the orbit. The globe was slightly raised. When removed the tumour was kidney-shaped, three centimetres long by two centimetres wide, definitely encapsuled, and made up of large spindle-shaped cells.

Dr. RAYNER D. BATTEN exhibited two cases of Serous Iritis with Tachycardia. The first patient, a girl, aged 14 years, had been one year under observation. The serous iritis was very marked and in January last a nodular deposit appeared in the inferior angle of the anterior chamber; this had diminished somewhat and become vascular. The tachycardia and thyroid enlargement had improved at one time and had then recurred. The second girl, aged about 20 years, presented well marked serous iritis with synechiæ of the iris, there was persistent tachycardia with enlarged heart, tremors, and flushings, but no distinct enlargement of the thyroid gland. Dr Batten had met with other cases of a similar kind, in one of which the patient suffered from a destructive sclero-keratitis with loss of the eye.—The PRESIDENT recalled two cases presenting this combination of symptoms.

Mr. G. HARTRIDGE exhibited a case of Choroiditis which had been shown in an early stage in December, 1893. Vision in one eye was $\frac{6}{6}$ and in the other $\frac{6}{60}$, though the fundus change in both seemed about the same.—The PRESIDENT referred to a somewhat similar peculiarity of vision in connexion with nebulæ; sometimes with a small area of cornea involved vision was very defective, while in others with an apparently extensive opacity the patient could see wonderfully well.

Dr. A. S. **PERCIVAL** showed a pair of Periscopic Glasses. The lenses being concave allowed of lateral movement of the eyes, provided the paper read was slightly curved, without the distortion usually experienced while using lenses ground on the flat. The curve was so arranged that the circle of confusion, developed when looking 25° right or left, was not larger than the maximum sectional area of a retinal cone 0 002 millimetre.

Mr. W. **LANG** showed an infant with a Congenital Notch in the outer part of the Left Lower Lid and Dermoid Growths on the Eye. The latter were flat and more loosely connected than usual.

Mr. **ADAMS FROST** exhibited a girl with a variety of Malformations about the Face. There was a quadrilateral gap in the right upper eyelid, the lashes being absent, while above the eyebrow was a tuft resembling them. The caruncle was deformed; at the outer canthus there projected a mass resembling a lobe of the lacrymal gland. The development of the external ear was defective on the same side, and though there was no meatus hearing was not entirely absent. A dermoid structure existed near the right angle of the mouth, also projecting on the inner aspect, and there was a dimple on the left side as if something had been removed. The eye was healthy; there was no coloboma of the choroid. —Dr. **JOHNSON TAYLOR** said that dermoid growths on the cornea sometimes had deeper connexions than were apparent and required to be handled with caution to avoid perforating the globe —The **PRESIDENT** recommended a blunt-pointed knife for the purpose.

Mr. C. **BLAIR** exhibited a Portable Refractometer which consisted of a spectacle frame carrying revolving discs fitted with glasses so arranged that an extensive range of lenses could be placed before each eye, saving time and trouble in retinoscopy and testing. The discs were five inches in diameter and the frame weighed eight ounces.

Mr. J. B. **STORY** showed a Thorn which had been buried in the iris at the edge of the anterior chamber for two months, the outer end being entirely obscured by lymph; when once discovered the removal had not been attended with difficulty.—The **PRESIDENT** said that he had found a splinter of wood in the anterior chamber of an eye that had been injured while the patient was chopping wood 12 years before. Some irritation had occurred on three occasions.

Mr. C. **WRAY** showed a case of Primary Chancre of the Lower Lid which had been inoculated by the finger-nail after scratching a specific sore.

Mr. **WRAY** also exhibited a man who had had Extensive Detachment of the Retina. There were 15 dioptres of myopia. The tunics of the eye had been twice punctured with a Graefe's knife at a fortnight's interval, after the manner described by Wolf. The eye in addition had been bandaged and instilled with atropin and mercury and chalk powder had been administered in two-grain doses thrice daily. The retina had become reapplied to the choroid and vision was $\frac{6}{60}$ and improving.—Mr. **MARCUS GUNN** said that the operation in question had been repeatedly performed before the account published by Wolf and could not rightly be associated with his name. In the present case there was still a little detachment and also some affection of the choroid resulting from the interference which no doubt assisted the re-attachment.—Mr. **JOHNSON TAYLOR** said that he had performed the operation two or three times, but he thought that in all the cases the patient's condition had been made worse —The **PRESIDENT** said his own experience had been disastrous. In one case in which he had advised against the operation the patient had since undergone three operations in Paris at considerable expense and vision was only equivalent to J. 19, though previously it was J. 8.

Mr. **WRAY** also exhibited a case of Doubtful Exostosis of the Orbit (with skiagrams).

Mr. **HOLMES SPICER** showed a case of Spring Catarrh in a Quiescent Stage. The appearance was quite typical, the milkiness of the lids and the granular condition of the conjunctiva being well marked and showing the characteristic hexagonal pavement appearance. The patient had spent three years in Johannesburg, having attacks each summer, but he had suffered most of all when crossing the line at sea on his return when exposed to the greatest heat.—Mr. **LANG** expressed his opinion that it was of the greatest importance that rather uncommon cases of this sort should be shown at the society. He had under his care at the present time a child who had, in consequence of this complaint, been subjected to a plastic operation which had resulted in ptosis, pannus, and iritis. Had the condition been recognised no such treatment would have been undertaken.

Dr. A. H. **THOMPSON** showed a case of Double Temporal Hemianopsia with Optic Neuritis which occurred suddenly at 5 A.M. three weeks ago in a young woman in association with the vomiting of pregnancy. The outer half of the visual field was lost in both eyes, which presented the characteristic hemianopic pupil reflex, no contraction taking place when light was directed from the temporal side, though it was manifest when thrown into the eye from the nasal side. The discs showed the changes of neuritis. The lesion was probably of the anterior part of the chiasma.—Mr. **GUNN** suggested hæmorrhage into the pial sheath.—The **PRESIDENT** thought the indications were against the supposition of tumour.

Mr. J. H. **FISHER** showed a case of Thiersch's Graft of the Orbit employed after removal of the globe, retro-ocular tissue and lids for sarcoma of the sclerotic. There had been three operations. The skin was obtained from the arm and a month after the operation it had covered the orbit, obviating at once the slow process of granulation and the unsightly contraction of the eyebrow. Three other cases had been treated in a similar way with equally good results by continental surgeons.

HARVEIAN SOCIETY OF LONDON.

Deciduous Dentition as a Factor in the Health of the Child.

A MEETING of this society was held on May 2nd, Dr. F. W. **COCK**, Vice-President, being in the chair.

Mr. W. H. **DOLAMORE** read a paper on Deciduous Dentition as a Factor in the Health of the Child. He said that he thought the importance of this dentition was hardly sufficiently recognised and he proposed to emphasise this by, first, considering the part played by the septic condition of the mouth, induced by caries of the teeth as a predisposing or exciting cause of diseases in the child. Of these he mentioned ulcerative stomatitis, necrosis of bone, and enlarged lymphatic glands, which latter might become the seat of tuberculous growth, whence the system might be generally infected. He also was of opinion that if in an adult gastric and intestinal diseases could be due to oral sepsis, *a fortiori* this would also be the case in a child. Secondly, he referred to the fact that for eight years, between the ages of two years and 10 years, the child was dependent on the deciduous teeth for the important part which the mastication of food played in nutrition and that hence these teeth should from the beginning be regularly cleansed and caries arrested in its early stages. To emphasise these points he quoted statistics comparing the growth of a child during the eight years, from two to 10 years of age, with a like second period—from 10 to 18 years of age. These figures showed the ratio of growth of the first to the second period to be for a male child 75 to 61, and for a female 75 to 42; whilst the fact that in spite of decreased growth the child during the second period increased in weight far more than during the first suggested, he considered, that during the earlier period the nutrition of the child was not in excess of absolute need. He drew from these data the conclusion that the mastication of food could not be interfered with by the decay and extraction of deciduous teeth without impairing the health of the child. He suggested that the matter was of sufficient importance to merit the attention of school authorities, especially of such as had to do with the children of the poor.

Dr. **COOK**, after thanking Mr. Dolamore for his most interesting and valuable paper, emphasised the points of earliest cleanliness with the use of the toothbrush and the absolute necessity of examination also from an early period of the deciduous teeth by a dental surgeon.

Mr. J. **SEFTON SEWILL** said that he cordially agreed with Mr. Dolamore in his conclusions. It was pitiable to see the terrible wreck presented by the mouths of most young children brought to the hospital. Ignorance of the importance of systematic treatment of deciduous teeth was, however, confined by no means to the poorer classes, many parents of good social position being quite surprised to learn that it was possible to treat temporary teeth conservatively. It was most important to fill temporary teeth as soon as decay was perceived, rapid onset of root absorption precluding in most instances the possibility of saving them after the pulp had become exposed. He could see no reason to doubt that the temporary teeth were as fertile a source of systemic trouble as were those of the permanent set; but though the part played by these latter was generally recognised, he believed that even in so excellent a paper as that read by Dr. William Hunter before the Odontological Society no mention had been made of the temporary teeth. It rested largely with the medical practitioner to advise parents of the importance of attending to their children's temporary teeth.

Dr. **ALFRED EDDOWES** expressed his belief that toxins collecting in carious teeth became highly concentrated and, just as by flowing backwards they set up tonsillitis and probably other throat troubles, so by flowing out of the mouth with saliva they frequently set up a circum-oral eczema which in some cases spread to all parts of the skin. He related a case of complete coma cured in a few hours by lancing a tense gum, and he said that he had seen a child pass highly acid, pale urine containing uric acid crystals apparently as the result of the worry and disturbance of teething. He asked if there was a better remedy than a little chloral dissolved in glycerine for application to the tender tense gums during teething.

Dr. **E. CAUTLEY** doubted whether teething ever gave rise to fits unless there was some strongly predisposing factor present The deleterious effects due to septic infection of the mouth and alimentary tract from carious deciduous teeth were seen constantly and bad teeth also produced digestive disturbance through the food being "bolted" instead of being properly masticated. He thought that suitable diet after birth was of value in maintaining the nutrition of the deciduous teeth and he regarded all artificial modifications of milk &c. foods as inferior to unboiled milk for this purpose. The boiling of milk did undoubtedly render the salts less soluble. Suitable diet and oral asepsis were the only preventive measures available after the birth of a child. A judicious diet for the mother during her pregnancy and while nursing was also of considerable value.

Dr. **C. S. JAFFÉ** and Mr. **HUBERT C. PHILLIPS** also took part in the discussion, and Mr. **DOLAMORE** replied.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Ether and Chloroform.

AN ordinary meeting of this institution was held on April 25th, the President, Mr. **EDGAR A. BROWNE**, being in the chair.

Mr. **D. DOUGLAS-CRAWFORD** read notes of a case of Gunshot Wound of the Femur with a Wound of the Popliteal Vein, and showed the patient, a young man, aged 17 years. The wound of entrance was on the front of the femur just above the patella; the wound of exit was in the popliteal space. The popliteal vein was lacerated and was tied and the lower end of the femur was comminuted. Five months later the lower third of the shaft of the femur was much sclerosed and an opening on its outer side led into a cavity three inches long and three inches deep. This cavity was reduced in size by means of bone grafting, sponge-grafting, and aseptic wax. The method of chipping the femur and packing the cavity with the pieces proved most useful in healing up this cavity.

Mr. **DOUGLAS CRAWFORD** also read notes of a case of Gangrene of the Hand Associated with Temporary Glycosuria. The patient, a male, aged 49 years, had pushed his arm through a skylight and had wounded the ulnar artery and divided the ulnar nerve. Gangrene set in in two days, and as there was no apparent local cause the urine was examined and was found to be loaded with sugar. The sugar was present for 48 hours, after which it disappeared. The arm was amputated and the patient did well.

Dr. **T. R. GLYNN** introduced a patient, a male, aged 40 years, with symptoms of an Aneurysm pressing on the Left Bronchus. The physical signs in this and other cases of a similar character were the development of emphysema with lessened vocal fremitus and vocal vibration and with feeble respiratory murmur throughout the left lung. If the aneurysm did not rupture and the patient survived for a time certain pathological changes occurred in the lung and the patient was likely to die with symptoms of chronic lung disease, cough, expectoration, hectic, &c. Drawings were exhibited of the left lungs of two patients who had died under the conditions referred to. In one the organ was the seat of a caseating pneumonia breaking down; in the other scattered tuberculous foci were present. The impediment to the entrance of air into the lung seemed to have been followed by the development of tubercle. He believed that the lesion in both cases was tuberculous in character, though it had not been proved, the patients having been under observation many years ago before the discovery of the tubercle bacillus

Dr. **GLYNN** also related a case of Paracentesis of the Pericardium on two occasions, with recovery. A boy, aged 17 years, had pleuro pneumonia 18 weeks before admission and had never recovered During the illness some clear fluid had been aspirated from the left side. The chief symptom on admission was dyspnœa (the respirations were 30 per minute when he was propped up in bed). The pulse, which was 120, was soft and irregular. Physical examination revealed dulness over the præcordium, extending 2½ inches to the right and 5 inches to the left of the mesial line at the height of the nipple, and lower reaching as far as the axillary line. The apex beat was absent, and the heart sounds were feeble. The temperature was normal. At the end of a fortnight the pericardium was aspirated and 14 ounces of clear fluid were removed. The urgent symptoms were relieved, the apex beat became perceptible, and pericardial friction sounds were audible for the first time. In a month's time the fluid had re-accumulated and 23 ounces of clear fluid were removed. On this occasion a mercurial manometer was used to estimate the pressure of the fluid in the pericardium, by means of a T-tube behind the aspirating needle. The pressure at the commencement of aspiration was + 2 1 centimetres, and at the end of the operation it was – 2 centimetres. No organisms were discovered in the fluid. The pericardial friction sounds again returned, but in a week or two these disappeared, and there was no evidence that the effusion had recurred. The patient left the hospital at the end of March, 1901, apparently well, but he had just been readmitted with a return of the effusion.—Mr **R. W. MURRAY**, Mr. **G. P. NEWBOLT**, Dr. **T. R BRADSHAW**, Dr. **J. BARR**, and Dr. **J. H. ABRAM** discussed the case and Dr. **GLYNN** replied.

Sir **WILLIAM M. BANKS** read a paper on Ether and Chloroform. Commenting upon the value of physiological experiments and statistical commissions he held that neither had been of the least use in aiding them in their search for the best anæsthetic or the best method of using it. Physiological experiments as to the effects of chloroform carried out on healthy animals could not form comparisons when dealing with diseased, anxious-minded, nervous human beings. The recently-published Report of the Commission on Anæsthetics of the British Medical Association did not disclose anything that they did not know before, but it was of value in preventing future investigators from going over the same ground. With reference to the question of dosage so much depended upon the idiosyncrasy of the patient and the knowledge of the drug and experience of its administration on the part of the anæsthetist that nothing could be expected from mathematical regulation of dosage. The fundamental principle in the giving of anæsthetics was "plenty of air and plenty of anæsthetic." Discussing the dangers of ether and chloroform he pointed out the danger of taking a long time to put the patient under with small doses of chloroform, for by the time anæsthesia was produced the patient had inhaled a large quantity of anæsthetic and had gone under very deeply. Sir William Banks considered that the great dangers were (1) overdosage; (2) too small an allowance of air; and (3) violent repression during the stage of excitement. With regard to ether the danger was in the accompanying secretion of sticky mucus, which was apt to choke up the respiratory passages, and the after-irritation of sickness. With regard to the methods of revival attention was drawn to the very markedly stimulating effect of rubbing the lips and nose vigorously up and down with a towel. As to the method of administration he thought that the simplest means and forms of apparatus were the best, and he advocated the administration of brandy in from one- to three-ounce doses given with very little water, immediately before anæsthetisation. If this was gulped down like a nauseous drug it would not be vomited. He mentioned the "dread" of the anæsthetic as being a bad preparation for the patient, and he pointed out that this was undoubtedly fostered by the knowledge of coroners' inquests. He suggested that the British Medical Association might well bring power to bear upon a coroner, so that if a death from an anæsthetic should be reported it should be treated in the same way as would be a death from operation, public inquiry being dispensed with unless there was cause to believe that there had been neglect or administration by an unqualified practitioner. Finally, he advocated more systematic teaching. Hospital anæsthetists should take a share in hospital teaching and should be entitled to a share of clinical fees. Each student should be required before getting his certificate of dressership to have his card signed by the anæsthetist to the effect that he had administered so many anæsthetics under supervision.—Mr. Rushton Parker agreed with almost all that Sir William Banks had said, and could not too strongly urge the closest attention to the respiration, and while giving plenty of anæsthetic vapour, giving also plenty of air by not holding the inhaler too close to the patient's face. It was also a most dangerous thing to allow fluids to enter the air-passages—a condition that might at any time occur insidiously and asphyxiate the patient. While all professed to be aware of this fact many failed to perceive it when it occurred. The state of the patient should be one of comfortable warmth also, as he had seen dangerous symptoms arise in the contrary condition, owing apparently to the consequently impeded general circulation. The value of prompt inversion when danger was sighted or suspected could not be over-estimated, and of all routine devices it was probably the safest, by allowing liquids to flow out of the air-passages and by favouring the nutrition of the circulatory and respiratory nerve centres. By "watching the respiration" he meant never allowing the slightest impediment to the due entrance of the necessary vapours to the lungs and their free exit.—Mr. F. W. Bailey, in reading the report of the Anæsthetics Committee of the British Medical Association had been struck by the number of methods of administration, amounting to 45 in all. He referred to the shock of extensive operations, the idiosyncrasy of patients, and the accumulation of mucus as all tending to contribute to the collapse that had been spoken of, and he strongly advocated the better teaching of the subject of anæsthetics. —Dr. J. E Gemmell agreed as to the greater safety of ether and he considered that the objections to its use—viz, the secretion of sticky mucus and struggling—were both obviated if the patient to begin with was placed with the head and shoulders raised, so that the act of deglutition could be accomplished without effort and if in the administration only small quantities of ether were used to begin with, say one drachm instead of half an ounce being put on the sponge at a time.—Mr. W. Fingland, Mr. R. G. Sheldon, Dr. F S Pitt-Taylor, Dr. A. C Rendle, Dr. W. M Cairns, Dr. Joseph Walker, Mr. A. B. Gemmel, Dr. Hamilton, Dr. F E. Marshall, and Dr. Barr also took part in the discussion and Sir William Banks replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Chronic Gastric Ulcer.—Unusual Cases of Pulmonary Disease.

A meeting of this section was held on April 12th, Sir George Duffey being in the chair.

Dr. William Calwell (Belfast) read notes of cases showing the effects produced by Chronic Gastric Ulcer. First a number of cases of perforation were cited; these all showed adhesions, in nearly every case strong and extensive, a thickened ring of indurated tissue around the perforation, and a history of years of gastric trouble. Three cases of very chronic adhesion, causing complete invalidism, were next detailed; these had been operated on, with considerable relief in two. Finally, three cases of dilatation of the stomach, due (certainly in one, probably in all) to pyloric or duodenal stenosis following ulcer and adjacent inflammation, were given. The conclusions drawn from a study of these cases were that better results would be obtained if a definite period were allowed for the trial of ordinary therapeutic methods, and that when the limit was reached exploratory laparotomy should be resorted to. As far as his experience went hydrochloric acid was absent from the stomach in cases of cancer.—Professor E. J. McWeeney said that for the last year or so he had tested the vomit from suspected cases of gastric cancer for hydrochloric acid in the Mater Misericordiæ Hospital, and the indication given by its absence was, in the main, found to be correct. Originally he had placed no faith in this test, but his recent experience induced him to alter that opinion.—Dr. Thompson said that last year he brought forward a case in which there were all the symptoms of acute perforating gastric ulcer, but on operation there was no sign of gastric ulcer to be found.

Professor James A. Lindsay (Belfast) read some notes on a series of Unusual Cases of Pulmonary Disease. The series included three cases of malignant disease of the lungs, two cases of pyo-pneumothorax with broncho-pleural fistula, a case of pneumonia with delay of crisis until the twentieth day followed by recovery, and a case of plastic bronchitis. In the first of the three cases of malignant disease of the lungs the primary deposit was in the gall-bladder; in the second the pulmonary invasion followed an osteo sarcoma of the knee-joint; and in the third the primary disease was scirrhus of the mamma. Cough, dyspnœa, and thoracic pain were present in all the cases and hæmoptysis in two out of the three. The physical signs presented much diversity. In the first case the signs were dulness, loss of breath-sounds, and diminished tactile fremitus over the affected area; in the second case the signs simulated those of phthisis and consisted chiefly of scattered areas of dulness and of crepitation in the right lung, the apex not being affected; in the third case the signs were for a time simply those of general bronchitis. In all the cases pressure signs appeared at a late stage. The difficulty of early diagnosis in these cases was dwelt upon. The most important points seemed to be thoracic pain, dyspnœa out of proportion to the physical signs, the nature of the expectoration, and the presence of physical signs of consolidation or infiltration in the substance of the lung or at the root The history was very important. The pressure signs, which made diagnosis easy, might appear only towards the close Emaciation, night sweating, and pyrexia might all be present in malignant disease of the lungs. The distinction from phthisis rested mainly on the absence of bacilli from the sputum, the nature and localisation of the physical signs, and the history and progress of the case. The duration of these cases was given by Walshe as 13½ months, which was probably an over-estimate. In the cases of pyo-pneumothorax with broncho-pleural fistula the point of interest was that each patient made a good recovery without operation. The question whether free incision and drainage should be practised in these cases was raised and discussed, but no decided opinion was expressed It was a question whether, with a free outlet for the pus through the trachea, the patients' prospects would be improved by the method of surgical procedure which succeeded so well in ordinary cases of empyema. In the case of pneumonia with delay of crisis to the twentieth day, followed by rapid convalescence, the patient was a boy, aged six years, in whom pneumonia of the left base was followed by pneumonia of the right apex without any break in the temperature, which remained at 105° F. for some time. The delayed crisis was no doubt due to the second attack having overlapped the primary attack. A delayed crisis might occur in senile patients without obvious cause or it might be due to some complication, especially empyema In the case of plastic bronchitis the symptoms were mainly those of spasmodic dyspnœa The casts varied in length from half an inch to one and a half inches, and in diameter from that of a coarse thread to that of a fine toothpick. The diagnosis rested entirely upon an examination of the sputum The patient made a complete recovery after residing for some time in the interior of Cape Colony. These cases were very rare and the medical treatment was unsatisfactory. The pathology was still unsettled.—Sir George Duffey said that plastic bronchitis was very rare. He had only known one such case; it occurred in a relative of his and the first symptom was hæmoptysis coming on suddenly.—Dr. Doyle said that he had had three cases of malignant disease of the lungs, one of them being under his care at the present time. In all of them extension had taken place from the breast. In the case now running its course there was no hæmoptysis and very little expectoration, but there was marked pain —Sir J. W. Moore, Dr. Travers Smith, and Dr. Dempsey also spoke.

Hull Medical Society.—The ordinary monthly meeting of this society was held in the board room of the Hull Royal Infirmary on April 12th, Mr. T. M. Evans, the President, being in the chair.—Dr.

E. M. Hainworth showed an Amputation Neuroma existing along with keratinous horn.—Dr. D. Lowson showed a Fimbriated Growth from the Knee-joint.—Dr. H. W. Pigeon showed (1) a case of Excision of the Knee-joint which had resisted other methods of treatment; and (2) a case of Hydrocephalus in which pressure on the pyramidal tract had been evidenced by the presence of Babinski's sign. He was treating the case by draining from the fourth ventricle and in the meantime with considerable success. Since draining the above sign had disappeared.—Dr. Hainworth suggested that a better means of draining might be into the arachnoid space, hoping thus to establish a communication between the ventricles. There would, he thought, be less danger of sepsis.—Dr. Eve read a short paper on Babinski's Sign, illustrated by cases and with an abstract of the literature on the subject. The sign consisted in extension of the toes, especially the great toe, when the sole was tickled. The sole should be warm and dry and the outer part should be stimulated. The presence of the sign enabled the diagnosis of organic disease of the upper motor segments to be made, but its absence did not disprove pyramidal tract disease. It was never present in health (except in infants) or in functional paralysis. It was invaluable in recent organic hemiplegia when the tendon reflexes were still slight. Dr. Eve had made the sign part of his routine examination in hospital work for a year and had observed no exceptions. He thought this sign of decided value, but he complained that in many cases the rivalry between the normal and pathological reflex (i.e., flexion and extension of the toes) left the nature of the response uncertain.—Dr. Lowson read a paper on a case of Ruptured Duodenal Ulcer. The patient was a girl, aged 15 years, with symptoms of perforation, and certain signs connected with the symptoms pointed to the duodenum as the ruptured viscus. Her illness began in the end of February with pain in the left side. A fortnight later she had a series of rigors with much depression and cyanosis about the lips and nose. On March 17th a sudden attack of profound collapse supervened with severe pain to the left of the umbilicus, feeble voice, great pallor, and cold perspiration. On the 20th there was a good deal of vomiting, consisting of bile and fragments of partially digested milk curd. This ceased on the 25th, when the temperature ran up, the pulse increased in rapidity and feebleness, and the whole abdomen distended slowly. Dr. Lowson was called in on April 4th. The patient had then a foul-smelling breath and a small and feeble pulse, and her breathing was quick, shallow, and thoracic. There was uniform distension of the abdomen, and below the liver to the right of the middle line there was a distinct localised swelling with the convexity forwards and extending below the level of the umbilicus which projected somewhat. There was much pain and tenderness over this prominence and at the umbilicus. On percussion the area of prominence was distinctly dull and the dulness joined that of the liver, which extended well up to the axilla and was bounded by the ordinary lung note. Here there was strong presumptive evidence of the rupture of a hollow viscus and the remarkable thing was that in a case of such magnitude the patient should survive three weeks. The following day the parents consented that the abdomen should be opened, but on examination Dr. Lowson found that a remarkable change had taken place in the physical condition of the patient. The localised swelling had disappeared and the area of dulness now gave a clear tympanitic note on percussion, while the liver dulness was normal. The patient had been intensely sick during the night and had ejected a large quantity of foul-smelling matter. Dr. Lowson thus explained the change. At the outset of the sickness the contents of the abscess were forced back into the stomach through the ruptured ulcer and ejected by the mouth, their place being taken in turn by gases from the stomach, hence the change from a dull to a tympanitic note. The abdomen having been opened by a vertical incision through the outer part of the rectus muscle, on first entering the peritoneum some gas escaped and then a gush of matter with some solid shreds, which was recognised as coagulated lymph, and pieces of partially digested food. The odour of this matter was most putrid. The cavity having been flushed and sponged out was found to be bounded by coils of adherent intestine covered with granulations on all sides except above, where the liver adherent to the edge of the thorax helped to form a boundary, and on the right side where the abdominal wall alone bounded the cavity. An offshoot of the general cavity extended to the left as far as the umbilicus and this Dr. Lowson thought might explain the tenderness in this situation. A rupture of the size of a No. 6 catheter was found in the duodenum and the contents were seen issuing from it. After disinfecting and scraping the granulations round the hole he inserted Lembert's sutures of fine silk, introduced a gauze drain, and closed the wound. There was now some pus still draining, but the condition of the patient was good. Dr. Lowson concluded by indicating the points of interest in the case. The patient's position in bed was favourable to the formation of adhesions and the issue of the contents was slow because the opening was a small one, hence none of the fluid got between the liver and the ribs, the former becoming firmly bound to the latter, thus preventing all access to its upper surface. There could therefore at no time have been disappearance of the hepatic dulness. Dr. Lowson's experience had led him to the conclusion that this was a sign of most uncertain occurrence requiring a copious out-rush of gas to produce it, or, at any rate, unless this took place not to be elicited at the onset of the symptoms, and (as in this case) where the liver adhered to the side it could not take place at all. He had arrived at the diagnosis of ruptured duodenum rather than the stomach from the rule laid down by Penrose and others that a subphrenic pneumothorax to the left of the falciform ligament of the liver was always gastric, while that to the right was always duodenal. The last point of interest was the situation of the abscess. As a rule, these were said to be situated immediately below the diaphragm and were called subphrenic pneumothorax or abscess. This case was then exceptional. The reason was that evidently, as a rule, the gas rushed out and separating the liver from its close apposition to the side allowed the exuding liquid to flow up between the liver and the diaphragm. But here apparently with a slow outflow and little gas, as shown by the dulness to percussion when first seen, the liver was not pushed away but remained in its normal position, while the acrid fluid washed its under surface and border setting up a perihepatitis in these parts. The liver thus became glued and ultimately firmly fixed to the side in its usual position. The whole process was exceptional in some points but was easily explicable and in every way most interesting.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on April 19th, Dr. Patrick Manson, the President, being in the chair.—Dr. Louis Sambon read a paper on the Principles Determining the Geographical Distribution of Diseases. After a reference to the inquiries and speculations of previous workers in this field, culminating in the classical treatise of Hirsch, Dr. Sambon said that it was necessary, in the first place, to have a clear conception of what constituted a disease. The nature of some diseases had been thoroughly investigated, but of others they really knew little. Specific organisms had been proved to be the essential causes of many infectious diseases and were properly assumed by strict analogy to be so in the case of others, though they had not yet been isolated and identified, but beyond this class bacteriology had afforded little help. The earliest parasite recognised was that of scabies, which was well known to the Arabian physicians, but in the West itch was explained by humoral hypotheses until in 1834, when the acarus was demonstrated by a Corsican student at Paris, and the latest discovery was that of the hæmatozoa of malaria. For the rest, the conventional classification of diseases according to the organs involved was unscientific, involving needless repetition; they ought to be described according to their causes, whether mechanical, chemical, parasitic, or otherwise, though this, of course, could not be done in the case of those the causes of which were ill-understood. Many, indeed, might be parasitic which were at present ascribed to totally different causes, e.g., gout and scurvy, which could not be wholly ascribed to dietetic errors, having a limited geographical distribution, and similar diseases being observed in beasts and birds. Others were deemed communicable or hereditary, but heredity meant infection. Leprosy was till quite recently held to be hereditary, as at one time were intestinal worms, while even syphilis was ascribed to meteorological influences. The study of the diseases of animals and of plants afforded evidence of the important part played by parasites, and lesions identical with those produced by alcoholism in man when met with in animals must find some other explanation. Cancer was probably parasitic, as also were many other so called neoplasms. Galls in plants, the parasitic origin of which was undoubted, presented striking resemblances to papillomata, epitheliomata, carcinomata, acromegaly, &c. The actual process was unknown, but the growth was not excited by the eggs, for it did not begin until they were hatched, and it ceased on the death of the larvæ. Probably all parasites were originally independent organisms, but once having become parasitic they underwent a process of specialisation, which, as in the limbless females of the strepsiptera, might be one of adaptation by degradation. Every animal and plant had its fauna and flora, and each parasite its host, one or less often two in succession. The areas of parasitic diseases were wide (typhoid fever, tuberculosis, dysentery), narrow (beri-beri), spreading (cholera, yellow fever), shifting (plague), or retiring, with change of conditions. Malaria had thus disappeared from England with the extinction of the anopheles and appeared with its introduction in Mauritius in 1868, while in Southern Italy it had subsided under the Roman Empire but had reappeared later. When animals and plants were supposed to have originated *in loco quo* climate was held to be the determinant factor, whereas we now knew it to be rather competition and adventitious aids, as the presence or absence of enemies, or in the case of plants of friendly insects or algæ. The parasitic nature of filariasis was shown by Dr. Manson many years ago, that of malaria by Major Ross quite recently, and it was now strongly suspected that yellow fever also depended on a hæmatozoon, having, too, its insect host. The spread of enteric fever in camps and its disappearance in the cold season were partly due to the action of flies in conveying infective matters in this, as, perhaps, in lesser degree, in diphtheria, small-pox, &c. The long immunity enjoyed by Europe from the plague was in part rightly ascribed to the advance of civilisation, but our knowledge of its laws was imperfect. No doubt sanitation in its widest sense would prevent the recurrence of "black deaths," but they had to reckon with rats and fleas. The connexion of the former with the spread of the infection, recognised by many native races of Asia, seemed to have been known to the ancients, for the Medes represented the god of the plague as riding on a rat, but it was not so as regards the flea, which was doubtless the immediate link between the rat and man, unless the strongly perfumed amulets and oiled linen worn by the Persians and recommended by the Arabian physicians during epidemics were intended for protection against their attacks. In conclusion, he maintained that the same laws governed the distribution of parasites and of other living things and predicted an ever-widening extension of the doctrine of parasiticism to the etiology and pathology of diseases in which it had not as yet been suspected.—Colonel Kenneth McLeod, I.M.S. (retired), pointed to Devonshire colic and the recent epidemic of peripheral neuritis in Lancashire as showing that local distribution alone was no evidence of a parasite causation, though, on the other hand, the limitation of elephantiasis arabum to littoral and insular climates was now explained to be dependent on climate only so far as this affected the distribution of the filaria and its other hosts.—Professor C. H. Stewart referred to the value of Pettenkofer's researches on the great influence of meteorological conditions on the prevalence and distribution of cholera, typhoid fever, and other parasitic diseases.—A Naval Surgeon remarked that the diseases with which he had to deal were mostly parasitic and were preventable by simple precautions; thus beri-beri attacked those men only who did not eat fat. It was a peripheral neuritis, and it was possible that the Lancashire disease also might be parasitic, the arsenic merely rendering individuals vulnerable thereto.—The President observed that alcoholism might be considered as a germ disease, being caused by a toxin formed by a microphyte though outside the body; such, too, was beri-beri. Dr. Sambon might have greatly widened the scope of his brilliant speculations if he had not treated germ diseases as exclusively parasitic, for many were due to micro-organisms altogether external. He remarked that the edible root of the potato was now held to be the result not of cultivation but of disease, a tumour caused by bacterial infection and not produced in plants raised from imported seeds and grown in sterilised earth.—Dr. Sambon, replying, remarked that peripheral neuritis appeared to follow so many causes that no one could be considered primary. In Italy it occurred as local epidemics that could not be explained by alcohol, arsenic, or any other of the commonly assumed causes.

Society of Medical Officers of Health.—A meeting of this society was held on May 8th, Dr. J. C. MacVail, the President, being in the chair.—Dr. Eustace Hill (medical officer of health of the county of Durham) read a paper on Sewage Disposal in Rural Districts by Bacteria Contact Tanks. He said that it was only quite recently that the true nature of the process of the transformation of the organic matter of sewage had been understood. For many years broad irrigation and downward intermittent filtration were the only methods recognised by the highest authorities, and they were still the most satisfactory where suitable and sufficient land was set apart. Even so late as March, 1894, a reviewer in *Public Health*, the official organ of the society, pronounced the Scott-Moncrieff process and the principles on which it was based—viz., the peptonising action of certain bacteria and the nitrification of organic matter by others—as "unworthy of serious attention," reserving his praises for processes which, aiming at the destruction of the bacteria, in direct opposition to Nature's method, have proved utter failures. About that time Mr. Dibdin's experiments on the treatment of sewage in coke filters and their practical application at Sutton in Surrey showed that the whole of the suspended, and most of the dissolved, organic matter could be removed from crude sewage by bacterial agencies alone without the use of chemicals. Mr. Cameron of Exeter also availed himself of the action of bacteria in his "septic tank," in which the sewage was submitted to peptonisation by anaerobes before being passed through filters for nitrification by aërobes. Dr. Hill then gave an account of his experience with the bacteria contact tank at South Moor, a mining village with a public water-supply guarded against waste but no baths or water-closets, the sewage being consequently concentrated, urinous, and soapy and not over 10 gallons per head. While the population did not exceed 1000, the sewage was satisfactorily disposed of by downward intermittent filtration on two acres of land, the effluent passing without offence into the Stanley Burn which provided part of the populous village of Chester-le-Street with drinking water; but when within the last few years the population rapidly increased to four times its former number the filtration was insufficient, the river became polluted, and an outbreak of enteric fever at Chester-le-Street suggested to Dr. Hill and the district surveyor the construction on the same site of contact tanks like those at Sutton, the beds themselves having an aggregate area of half an acre and treating daily a dry-weather volume of 46,000 gallons of sewage from 4600 persons, to which storm waters were from time to time added to several times the volume of the sewage. The sewage was passed through a small detritus chamber and a half-inch vertical screen to a subsidence tank 35 × 39 × 5 feet and holding 24,000 gallons, or about half the daily discharge. When this was full, usually after 12 hours, it was discharged on to the surface of the coarse filter-tanks in rotation. There were four of these, of brick and concrete, each 43 feet square by five feet deep, their total area being 820 square yards and their capacity 185,000 gallons. They were filled with broken and screened coke breeze and clinker from one to two inches in diameter, the capacity of each for sewage being a little over 20,000 gallons. On the floor of each was a diagonal network of open-jointed drain pipes, and an outlet pipe with screw-down valve communicated with a central chamber from which the effluent was conveyed by a channel to, and discharged over, a weir into the fine filter-tanks, the construction and arrangement of which were similar to those of the coarse filters, save that their area was larger and their depth less, being three feet only, the capacity of each for liquid being 25,000 gallons, and the filtering material being screened to a size of from a quarter of an inch to one inch. The collecting pipes were fewer and the effluent pipe, when its stop valve was opened, discharged directly into the stream. The height of the liquid in the several tanks was seen in four-inch drain-pipes standing vertically in each. As each filter tank was emptied the air taking the place of the liquid supplied the oxygen necessary for the activity of the microbes. At first the sewage was, as at Sutton, held up in the successive tanks for not more than four hours, but it having been found that the nitrification of the night flow remaining undisturbed for 12 hours was more perfect longer periods of contact, from eight to 12 hours, had since been adopted with the best results. Dr. Hill's inquiries as to the working of automatic arrangements elsewhere had not been satisfactory, and he relied at South Moor on an intelligent attendant.

The final effluent was invariably clear, bright, and wholly devoid of smell. From the first the results had been highly satisfactory, but since May, 1899, when after three months' working bacterial action was fully established, the organic ammonia had averaged 0 072 part per 100,000. Analyses of the effluent taken after many days showed the absence of further putrefactive changes and that there was no need for subsequent filtration through the soil—a condition of all loans from the Local Government Board. The whole cost was accordingly paid out of the current rates and it worked out at no more than 7*s.* 3*d.* per head of the population, while that of maintenance and the services of the attendant for three or four hours daily was but £30 per annum. The nature of the material used for the filters, whether coke, clinker, burnt ballast, or crushed rock, was of no importance, nor was the size of much moment provided that it was not too small, not under a quarter of an inch in the fine filter. There must be a difference of level of at least eight feet between the sewage and the outfall, or, if as at South Moor a collecting tank were interposed, of 12 feet. Where this could not be had it would be well to substitute the septic tank, which should discharge its effluent on to a fine filter bed for nitrification.—Dr. H. R. Kenwood said that the installation described by Dr. Hill was working under very favourable conditions, for the coarse beds were fed at a rate not exceeding from 90,000 to 100,000 gallons per day per acre, and though the sewage was strong their work was greatly lightened by the previous sedimentation. He preferred the principle of automatic mechanism, duly supervised, to manual labour alone, as tending to greater regularity in the feeding and emptying of the beds — Remarks were also made by Dr. J. W. Hombrough (Northumberland), Mr. Richards (Croydon), Mr. Beale Collins (Kingston-on-Thames), and others.

Hunterian Society.—A clinical evening of this society was held on April 17th, Dr. Dundas Grant, the President, being in the chair.—Dr. W. J. McC. Ettles showed a case of Ascites lasting since 1897. In February of that year the patient, a female, underwent an operation at the London Hospital and six weeks afterwards a second operation. She then came under the notice of Dr. Ettles who had since tapped her 28 times and had removed 566 pints of fluid At first the interval between each tapping was three and a half months and 29 pints of fluid were removed at a sitting. Now only six weeks elapsed and only from 16 to 18 pints were removed. A hard mass could be felt in the hypogastrium after the abdomen was emptied. There was no swelling of the ankles, hence the obstruction must have affected the portal vein only.—Mr. J. H. Targett quoted two cases which occurred some years ago in which there had been some hundreds of tappings performed at intervals of from 10 days to three weeks. In both of them double papillomatous growths of the ovary were found.—Dr. Ettles next showed a case of Tumour over the Right Clavicle of Doubtful Origin. Two and a half years ago the patient had syphilis. The Crookes tube and fluoroscope were applied to the patient during the meeting and marked swelling of the clavicle was seen, thus pointing to the probability of the tumour being a gumma of the periosteum —The President, Mr. H. L Barnard, Dr. T. Glover Lyon, Dr. Adams, and Mr. H. W. Carson discussed the case —Mr. Barnard showed a case of Spiral Fracture of the Tibia The patient, a man, aged 44 years, fell while carrying a sack of coals downstairs. He was admitted to the London Hospital with a fracture of the right tibia in the lower third and of the fibula in the upper third. A skiagram showed the fracture of the tibia to be a spiral one. For 10 days every effort was made to fix the fragments in a good position upon splints, but without success As the patient recovered from the anæsthetics the fragments slipped over one another and the lower end of the upper fragment threatened to perforate the skin and to make the fracture compound. The following operation was therefore performed 10 days after the accident. An incision half an inch long was made down to the subcutaneous surface of the tibia and one and a half inches above the pointed end which was threatening to perforate the skin. The fragments were firmly held by an assistant in as good a position as possible. A drill which was only a little smaller than the screw was then driven across the fragments obliquely. As the drill was withdrawn the screw was slipped into the hole and screwed home. It was felt to draw the fragments together and to lock them firmly. The sharp lower end of the upper fragment retreated from the skin. A cyanide gauze dressing was applied and the leg was placed upon a back splint with a foot piece. The screw was silvered steel. After 10 days the leg was put up in plaster and the patient went about on crutches. The screw was removed six weeks after it had been inserted. It could not be withdrawn like a nail or a tooth, but required to be unscrewed. It is better to remove such screws, as even after years they may give rise to abscesses, sinuses, and necrosis. The result of this simple operation, as viewed by the fluoroscope at the meeting, was seen to be good. The fragments were in line, firmly united, and there was no redundant callus.—Dr. Glover Lyon showed three cases upon an x-rays screen. The first was a case of Aneurysm of the First Part of the Aorta which two years ago had not been discovered upon first examination, but was at that time rendered plainly visible upon the fluoroscopic screen. The second case was one of Arrested Phthisis of six years' duration, the patient being now nearly a stone heavier than when first seen. The third case showed a generally Dilated Heart. The x-rays apparatus used at the meeting, lent and worked by Mr Harry Cox, was fitted with the Mackenzie-Davidson break and gave perfectly steady shadows upon the screen.

Rochdale and District Medical Society.—A meeting of this society was held on May 2nd.—Mr. W. Pooley showed specimens of a Dermoid Cyst which had simulated spina bifida The patient, a girl, 17 years of age, complained of a painful tumour at the lower end of the spine on the left side. A corresponding tumour on the right side had been removed in infancy. The patient had never attended school because she could only sit by crossing one leg under her and sitting on that. Examination showed a globular swelling over the sacrum of the size of a large orange The size was the same whatever the position of the patient. There were three or four sinuses discharging pus. The legs were well developed; there was no loss of control over the rectum or the bladder. The curve of the sacrum was exaggerated. Nothing abnormal could be detected per anum The diagnosis of spina bifida was made and it was decided to remove the tumour. The operation was tedious, the skin being adherent to one-third of the surface. During dissection some of the contents of the cyst escaped and hair presented at the opening, showing the true nature of the tumour. A piece of bone was adherent to the sacrum The case was one of "sequestration dermoid."—Mr. Pooley also showed a Testicle removed for Tuberculous Epididymitis —Dr. D. Richmond showed a Cyst of the size of a fœtal head removed from the right lobe of the thyroid gland of a woman, aged 60 years There had been a swelling for 30 years, but it had increased greatly during the past two months and was causing difficulty in breathing. The contents of the cyst were fluid débris and calcareous material. —Dr. W. J. Kerr read notes of a case of Round-cell Sarcoma of the Right Orbit pressing the eyeball down and out. There was some sloughing of the cornea. It was found impossible to remove the tumour with the globe in position, so enucleation was performed and the tumour was removed apparently completely. It recurred, however, in a few days. An attempt to remove a corresponding growth on the left temple was ineffectual owing to deep connexions, but no further growth occurred on that side. The patient, a boy, died three months later. He had become very anæmic and he suffered from hæmorrhages from the mouth and nose.—Dr. Kerr also mentioned a case of Strangulated Femoral Hernia, in which flatus was passed three hours after operation, followed shortly afterwards by free movement of the bowels. Motions followed in rapid succession, and, in spite of treatment, diarrhœa set in and lasted nine days, when the patient died from exhaustion The wound healed perfectly, there was no rise of temperature and only a little vomiting on the sixth day —Dr. Richmond and Mr. Pooley had each had a similar case.—Dr. Kerr exhibited sections of Alcoholic Livers showing Cirrhosis and Fatty Changes. He also exhibited a section of Liver showing Typical Cirrhosis from a man who died at the age of 44 years from the condition The patient was a life-long teetotaler and had not had syphilis —Mr. Wilton Mills mentioned a similar case of cirrhosis in a total abstainer.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on April 16th, the President, Mr. F. Farrow, being in the chair.—Mr. W. H.

Horrocks read notes on two cases of Hypertrophy of the Breast. One of the patients was an unmarried woman, aged 22 years, who was admitted to the Bradford Royal Infirmary on Oct. 31st, 1898, complaining of enlargement of the right breast of 12 months' duration. It had been painless till 14 days before admission, when it had become red and painful and there had been a slight rigor. Her general health was good and the catamenia were regular. There was very great enlargement of the breast but there were no enlarged glands. The breast was amputated and the wound healed without trouble. The left breast was small and ill-developed. The other patient, a married woman, aged 21 years, was admitted in April, 1899, complaining of enlargement of both breasts. The catamenia were regular till five months before admission when she became pregnant. The breast had always been rather large since puberty and rapid increase in size began in the second month of pregnancy, rendering her miserable from the great weight and constant dragging pain. Both breasts reached almost to the umbilicus when she sat up. The circumference of the right breast at the base was 29 inches and that of the left base was 30 inches. The right breast was amputated on April 21st. The wound healed readily. Eleven days after the operation she was delivered of a five and a half months fœtus. The left breast was amputated on June 21st as it caused great trouble from its weight and its unsightly prominence. The wound healed readily.—Dr. Jason Wood read notes on two cases of Moveable Kidney giving rise to severe symptoms. One of the patients was a married woman, aged 38 years, very tall and stout, who had enjoyed good health till 18 months ago when she was seized with severe pain in the left hypochondriac region. The left kidney could be palpated for about half its extent and was tender. With a few days' rest and the wearing of a pad relief was obtained. There were no further symptoms till two months ago when she was again seized with pain and tenderness which passed off in about a week with rest in bed. The other patient was a married woman, aged 38 years. When seen on Oct. 6th, 1900, she had a temperature of 102° F. and a dry brown tongue; she vomited and was constantly passing bloody urine. There was a large swelling in the right hypochondrium which was excessively tender. On the 8th she was much better. On the 11th the tumour was smaller, moved freely, and felt like a kidney. On the 15th both kidneys could be palpated over the lower half and there was no pain or tenderness.—Dr. F. W. Eurich read a paper on Some Types of Locomotor Ataxia.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held at 20, Hanover-square, London, W., on April 25th, Dr. A. J. Harrison, the President, being in the chair.—Dr. C. Herbert Thompson (for Dr. J. H. Stowers) showed a case of "Erythema ab Igne" in a young woman who was accustomed to take very hot baths, but had not been exposed to radiant heat sufficient to explain the cause of the eruption.—The President considered the eruption could not be produced by the hot baths.—Dr. E. G. Graham Little showed a case of a circumscribed patch of Lupus Vulgaris of the size of a sixpence on the cheek of a boy, aged 10 years, of almost identical appearance with the case shown to the society by Dr. Stowers some four months ago.—Mr. George Pernet showed cultures from the case of Ringworm in a young woman, aged 23 years, which was brought forward by him at the last meeting of the society, and gave a demonstration of the means of differentiating the types of ringworm met with in this country.

Reviews and Notices of Books.

The Law Relating to Poor-law Medical Officers and Vaccination. By M. GREENWOOD, M.D. Brux., LL.B. Lond., of Lincoln's Inn, Barrister-at-Law. London: Baillière, Tindall, and Cox. 1901. Pp. 104. Price 2*s.* 6*d.* net.

THIS is a work published under the direction of the council of the Poor-law Medical Officers' Association of England and Wales in order to provide a handbook for the use of Poor-law medical officers that will inform them upon questions which may occur to them relating to the duties of their office, and which will contain its information in such a form that it may be readily consulted and easily understood. Such information has hitherto been mainly available in more or less weighty volumes compiled by lawyers for lawyers, and from which information upon the various branches of the subject treated of can only be dug out by dint of research, while the research can only be conducted with reasonable speed and with any certainty by those who have had training and practice in similar operations. As far as it goes the small volume which Dr. Greenwood has produced, and to which the title has been given of "The Law relating to Poor-law Medical Officers and Vaccination," is capable of conveying to Poor-law medical officers and public vaccinators useful information in a compendious form, much of which they will be glad to acquire readily, particularly when first approaching the duties of their appointments. It is written in a clear style, it gives the author's opinions or deductions so that they can be understood and followed, and little or no space is wasted by the citation of authorities to which the reader is perhaps not likely to wish to refer. On the other hand, it is a handbook only and a small one at that, while, although it is possible to overburden a book for the use of those who are not lawyers by profession by the citation of law reports and by references to statutes and sections, it is to be remembered that a medical man in a difficulty as to his legal position may at times want to rely upon the precise wording of an Act of Parliament, or to refer an adversary to an authority that will convince him. Sometimes the quoting of all material sections of an Act of Parliament, with brief notes in small print, a method commonly adopted in legal works for the use of lawyers, will give quite as clear an exposition of the law as a paraphrase or summary of it, and one less likely to omit matters which occasionally, though perhaps not often, it may be useful to know. As an example of what we mean we may refer to a brief summary of the position of the person known as the "conscientious objector" to vaccination at p. 42 of the little book before us. It seems to us to contain little more than is known already to most people, whether medical men, lawyers, or parents. Quotation of Section 2 of the Vaccination Act of 1898 would have shown that the unwilling parent before he is exempt from penalties has not only to satisfy the magistrates specified that he conscientiously believes that vaccination would be prejudicial to the health of the child, but also to deliver within seven days to the vaccination officer for the district a certificate by such justices or magistrates of such conscientious objection. We may have overlooked reference to this delivery of the certificate to the vaccination officer in the perusal of the work before us, but reference to the index does not enable us to discover it, although the duties of the vaccination officer (a layman) as well as those of the public vaccinator (a medical man) are treated of. Again, to take an example at random of a case in which a public vaccinator might desire to ascertain his duties, we do not recall, nor do we find by reference to Dr. Greenwood's index, any mention of what is to occur where a child has been successfully vaccinated by an unqualified person and the parent seeks the certificate from the public vaccinator that will exempt him from prosecution. This, we believe, is regulated by the seventh and twelfth sections of the Vaccination Act of 1871, the public vaccinator giving the certificate if he chooses, but not being compelled to do so, and being able in such a case to make his own terms as to the payment of a fee for the certificate by the parent who asks for it. We are quite aware that it is possible to overload a handbook with learning and with over-full quotation from Acts of Parliament and Orders, but at the same time in dealing with vaccination we have to bear in mind that where legal proceedings are taken to enforce it defences of a technical description are very frequently successfully raised by legal practitioners who have the technical duties of the public vaccinator and the vaccination officer at their fingers' ends, and who are ready to take advantage of the smallest technical omission or mistake on the part of anyone connected with the prosecution. It is as well, therefore, that those who have to do with the carrying out of the law of vaccination should be fully informed as to technical points and should have them constantly and clearly before their eyes. The medical practitioner who wishes to become a district medical officer, or workhouse medical officer, or public vaccinator will, however, find a good deal that he may wish to know explained by Dr. Greenwood and will be able further to study in the appendices at the end of Dr. Greenwood's work forms of contract such as will be used by him and by the guardians with whom he agrees to fulfil his duties; he will also if he be, or intends to become, a public vaccinator, find some general remarks and suggestions, compiled at the request of the Poor-law Medical Officers' Association by Dr. A. E. Cope, which, while not forming part of the law relating to his office, may be of use to him in his performance of its duties.

Fractures. By CARL BECK, M.D., Visiting Surgeon to the New York German Poliklinik, and formerly Professor of Surgery in the New York School of Clinical Medicine. With 178 Illustrations. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 327. Price 15*s.*

THIS excellently got up treatise on fractures is dedicated to Professor Wilhelm Conrad Roentgen, "without whose discovery," says the dedication, "much of this book could not have been written." We may go further and say that the discovery of the x rays was the reason obviously of writing the book. The sections of our surgical manuals dealing with the diagnosis and treatment of fractures and dislocations which were written before Roentgen's valuable discovery were necessarily illustrated largely from the cadaver. Displacements of fragments, if fairly gross, can be ascertained by sight or palpation; in many fractures obvious deformities are present, their reason being very generally furnished by the muscular attachments; while in other fractures pain in certain regions and motional disabilities of certain sorts are characteristic. Before the discovery of the x rays surgical handbooks could only deal with the diagnosis of fractures as illustrated in the experience of their authors by these different signs and symptoms. Fractures and dislocations were generally discussed together, the aim of the association being differential diagnosis, and anatomical proofs being furnished from the dissection-room in proof of the conditions that were supposed to be existent. But the x rays in many instances enable the surgeon, familiar with the manipulation of the apparatus, to detect exactly what fracture is present and to deduce the cause of any deformity. The diagnosis that was wont to be a matter of doubt, only to be arrived at after the elimination of several, even of many, alternatives, may now be made without a possibility of error in a few minutes. It is from this improved surgical position that Professor Beck writes his handbook on fractures and the result is a very interesting work, though we doubt if many surgeons have found skiagraphy quite such an infallible finger-post to diagnosis as he has found it. The accurate recognition, for example, of fractures of the pelvis or of the base of the skull is not, in our opinion, much helped by the x rays. In each set of fractures it is occasionally easy to understand exactly what injury is present without recourse to any but the slightest manipulation, but we very much doubt if the x rays could be invariably depended upon to give the differentiation between the various lesions—fractures, dislocations, and simple contusions—that may occur about the hip-joint. Professor Beck admits that fractures of the base of the skull are still with difficulty demonstrated, and, for our part, we have never seen any skiagrams which illustrated the condition at all convincingly.

The book is a useful adjunct to treatises upon general surgery, and while it is intended to show that Roentgen's discovery created an epoch it really shows that the work of former observers has been so careful that many generations of surgeons have treated fractures with a perfect knowledge of the conditions although they were unable to avail themselves of skiagraphy in proof of their surgical faith. The illustrations are beautiful and we assume that the original skiagrams of which they are reproductions have not been unduly touched up.

Manual of Diseases of the Ear, including those of the Nose and Throat in Relation to the Ear, for the Use of Students and Practitioners of Medicine. By THOMAS BARR, M.D. Glasg., Lecturer on Diseases of the Ear, Glasgow University; Senior Surgeon to Glasgow Hospital for Diseases of the Ear, &c. Third edition, revised, and partially rewritten. With 236 Illustrations. Glasgow: James Maclehose and Sons. 1901. Pp. 454. Price 12*s.* 6*d.* net.

THIS valuable work has passed through an honourable probation, and has established itself in the forefront of text-books on the ear. Dr. Barr distributes the anatomical portion of the text through his work, instead of making it a separate part. This arrangement has the advantage of preparing the student for a consideration of diseased conditions with the normal state of each part fresh in his memory. We think that in no other text-book on diseases of the ear will such a clear and useful description of the more severe intracranial complications of aural suppuration be found as that given by Dr. Barr. The chapters devoted to the consideration of nasal and naso-pharyngeal affections are kept admirably within due limits, all extraneous matter being omitted. The above are but two points in a work that is of the highest order throughout, though we may perhaps take exception to the introduction of illustrative cases which we believe is not helpful to the student and adds unnecessary length to the book. Dr. Barr is to be congratulated on his manual; it is thorough, and will be found invaluable to those for whom it is written—students and practitioners.

The Asphyxial Factor in Anæsthesia, and other Essays. By H. BELLAMY GARDNER, M.R.C.S. Eng., L.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1901. Pp. 63. Price 3*s.* net.

THE first essay gives the title to this little book. It presents the author's views upon the undesirable symptoms arising when, through faulty administration of the anæsthetic, the patient does not obtain sufficient oxygen. The author's personal experience appears to agree with that of most other writers upon this well-worn subject. Students will no doubt find the rules laid down useful. For a wider circle of readers the omission of all reference to the scientific work which has been done from the time of Bichât and Reid down to the present militates against the value of the essay. The paper dealing with nitrous oxide gas given with oxygen in general surgery is better written and of interest. We gather that this mixture has not proved of so much value for cases lasting over a few minutes as it has done in dental surgery. The remaining part of the book does not present any very novel features. The essays as a whole are a meritorious effort to enforce the necessity for attention to detail and the appreciation of dangers which lurk in the careless use of anæsthetics. They show that Mr. Gardner has carefully studied his cases and has arrived at his conclusions as a result. From the surgeon's point of view we cannot endorse his experience that the best position for the patient for whom an empyema thoracis has to be dealt with is "almost on his face, with the diseased half of the chest lowermost." The use of the expression "stages of anæsthesia" for "degree of narcosis" is, as Snow pointed out, objectionable and misleading. Mr. Gardner is a painstaking and intelligent worker in his field of medical science and has produced a book which will prove useful to the student and tyro in anæsthetics.

Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Neuritis," and other Septic Conditions. With Illustrative Cases. By WILLIAM HUNTER, M.D. Edin., F.R.C.P. Lond., Senior Assistant Physician to the London Fever Hospital; Physician to the Electrical Department, Joint Lecturer on Practical Medicine and Pathological Curator, late Pathologist, Charing-cross Hospital. London: Cassell and Co., Limited. 1901. Pp. 30.

THE object of this book is to direct attention to the importance of septic conditions of the mouth as a cause of disease. Dr. Hunter has given considerable attention to this subject, and has succeeded in showing that certain general conditions, such as pernicious anæmia and gastritis, are at times traceable to infection from the mouth Dr. Hunter considers that he has met with cases of "neuritis" arising from septic oral conditions, but the examples which he quotes are not conclusive. The book, however, is instructive and is worthy of perusal by all medical and dental practitioners.

A Handbook of Materia Medica, Pharmacy, and Therapeutics. By SAMUEL O L. POTTER, A.M., M.D. Jefferson Med. Coll., Phil., M.R.C.P. Lond., formerly Professor of Medicine, Cooper College, San Francisco. Eighth edition, revised and enlarged. London: Rebman, Limited. 1901. Pp. 950, 8vo. Price 21*s*. net.

WE are glad to welcome another edition—the eighth—of this valuable work. It has been closely criticised and thoroughly revised, and much new matter has been added as a result of two years' medical practice in the tropical Philippines. We feel that we may recommend the book to British practitioners with the utmost confidence, though, of course, they must bear in mind that the word "official" throughout refers to the United States Pharmacopœia and not to our own.

The arrangement of the matter is in some respects unique, and will be found to make reference an easy matter. An elaborate classification of medicines is given in the first part of the book, and the definitions of each heading are thoroughly lucid and scientific. In dealing with individual drugs the physical properties and chemical constituents are first briefly described, a list of the official preparations follows, while important unofficial preparations are not forgotten. Next the physiological action in each case is described, and the therapeutics proper follow. The effects of toxic doses and physiological and empirical antidotes are also given. It will be seen that the work is nothing if not thorough. The second part of the book, devoted to "Pharmacy," is also valuable and will be found to contain an enormous amount of detailed information and good advice to the student on the writing of prescriptions.

The third part is entitled "Special Therapeutics," and in its compilation a very large number of the works of accepted authorities have been laid under contribution. It forms a very complete and reliable index of treatment which will be a godsend to many a busy practitioner who has no time to wade through the copious literature that accompanies each new drug into the market. A long list of the supposed or already discovered ingredients of various quack preparations is given at the end of the book, together with some tables of differential medical diagnosis and a most carefully-prepared index. We quite agree with the author that, however excellent a book, its value as a work of reference is small unless it possesses a thoroughly good index. But the tables of medical diagnosis seem to be hardly in place in this work on materia medica, and in their presence lies the one and only objection to the book, which is well written, well arranged, and printed on good paper.

JOURNALS AND MAGAZINES.

Scottish Medical and Surgical Journal.—The opening article in the May number is a description of the Clinical Features of Myasthenia Gravis by Dr. Edwin Bramwell of Edinburgh, who has examined nine cases of the disease. He states that up to the present time only some 80, or possibly 90, cases have been reported. In a paper on Twin Pregnancy Dr. Alexander MacLennan of Glasgow says that a diagnosis of twins can readily be made by abdominal examination. Apart from the size of the abdomen, which may be excessive, it is from palpation that the presence of twins can be most easily recognised. The shape of the uterus may be unusual. There may be a groove at the fundus, as has been pointed out by Kuncke, or the conformation of the uterus may be irregular. Fœtal movements, produced by more than one set of limbs and felt at different places, are also more or less characteristic. Two areas of maximum intensity of the heart sounds, separated by an area of silence, point towards there being more than one ovum; hearing two fœtal hearts having different rhythms is conclusive evidence. Dr. J. C. Dunlop of Edinburgh writes on the Food Requirements of Varying Labour, his data being obtained from prison experience. He considers that for moderate labour a diet of 3500 calories is insufficient, one of 3900 is excessive, and one of 3700 is sufficient without being excessive. Dr. H. O. Nicholson of Edinburgh contributes an article on the Sphygmographic Appearances of the Pulse in Infancy.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, F.R.S. Vol. xxvi., No. 5. London: C. J. Clay and Sons. April 24th, 1901. Price 7*s*.—The contents of this number of the Journal of Physiology are: 1. Galvanotaxis and Chemotaxis of Ciliate Infusoria, by H. H. Dale, B.A., Coutts-Trotter Student and Scholar of Trinity College, Cambridge. Part I. with 49 figures in the text. 2. The Action of Ether and Chloroform on the Cerebral and Spinal Neurons of Dogs, by Hamilton Wright, M.D., Director of the Pathological Institute, Federated Malay States. Supplementary papers: 3. On Dilatation of the Pupil from Stimulation of the Cortex Cerebri, by J. Herbert Parsons, B.Sc., Research Scholar of the British Medical Association, with two figures in the text 4. The Physiological Properties of the Muscle of Echidna Hystrix, by H. G. Chapman, M.B., B.S. (Melbourne), with eight figures in the text. 5. A Further Inquiry into the Supposed Existence of Cerebral Vaso-motor Nerves, by Leonard Hill, F.R.S., and J. J. R. Macleod, M.B., with 11 figures in the text. Lastly, the Proceedings of the Physiological Society on Feb. 12th and March 16th are given.

Mercy and Truth.—Dr. Minnie Gomery writes on the prospects of medical work at Islamabad in Kashmir. Dr. T. L. Pennell has an illustrated article on the Bannu Medical Mission in 1900. Bannu is in the Punjab. In the hospital there were 607 in-patients with 18 deaths. In the out-patient department 43,100 visits were made.

Friend of China.—The April number deals chiefly with the annual meeting of the Society for the Suppression of the Opium Trade held in Exeter Hall on Feb. 26th. The publishers are Messrs. P. S. King and Son, Westminster.

THE LANCET.

LONDON: SATURDAY, MAY 11, 1901.

Enteric Fever and Food-supply.

WE are always learning of new channels by which the virus of the acute infectious diseases may be conveyed to man. Before the majority of us were born it was a well-recognised fact that water was a frequent vehicle of infection. Later it was found that milk served to disseminate enteric fever, then it became clear that a similar charge could be brought against ice-creams and shell-fish; and now we are presented by the London County Council with a report in which fried fish is accused of behaving in the same manner. The report deserves careful consideration, not only on account of the extreme importance of the subject-matter concerned, but because the investigation which has led to this conclusion has been made by a competent observer. The report relates to three outbreaks of enteric fever occurring respectively in September, 1900, in Southwark, and in the latter part of August and in September in Lambeth and in Kensal Town. The Southwark outbreak furnishes the most valuable material for etiological investigation because a larger number of persons were attacked and because the social condition of the persons living in the infected area was more uniformly the same throughout the whole of it than in the other areas. This outbreak, therefore, best deserves consideration, for the extent to which Dr. W. H. HAMER'S conclusions concerning its cause are accepted must govern the view that is entertained of the soundness of his conclusions as to the other outbreaks.

In Southwark in the course of three weeks about 100 people were attacked with enteric fever. They were all poor people, living and eating as poor persons do, and subject to that amount of prevalence of enteric fever which usually manifests itself, especially in the poor districts of London, at that period of the year. The suddenness of the outbreak and the rapidity with which the residents of a small and fairly compact area were attacked undoubtedly suggested that the disease was caused by an infected food-supply, and Dr. HAMER'S inquiries were consequently directed to determining whether the cause of the attack of this considerable number of people was water, milk, ice-creams, or shell-fish. The facts ascertained, however, completely failed to show that these possible causes had been operative and hence attention had to be directed to other possibilities. Among these was the excellent habit of the younger people of resorting to public baths, but examination of the relation between bathing and the incidence of the disease failed to show any association. Lastly, Dr. HAMER was led to make detailed inquiry into the relation between the incidence of the disease and the consumption of fried fish from a particular shop, and here he found so close a connexion that this relationship was fully investigated. It then became evident that there was a parallelism between the consumption of fried fish and attack by enteric fever that is not explicable on any other hypothesis than that the two stand in the same relation as cause and effect; for not only did people visiting the fried fish shop suffer out of all proportion to others, but persons in their own homes to whom the fish was brought suffered, while other members of the same families who did not eat fish escaped. Dr. HAMER has not professed to account for every single case of enteric fever which has occurred in the affected area on this hypothesis. Some small number of "secondary cases" occurred, caused no doubt by an antecedent case in their homes, itself possibly due to infection from fish. Again, a much smaller number of cases occurred for which explanation was wanting, but these were not more numerous than might well have arisen without any cause other than those which govern the autumnal prevalence of enteric fever in the London population. Indeed, Dr. HAMER'S hypothesis must be accepted or the method of statement of the circumstances of the case contains some fallacy. In the main it is an arithmetical statement of the incidence of the disease upon two populations living under identically the same conditions, except in respect of the habit of eating fried fish. It is the method which was adopted by Sir JOHN SIMON in his investigation of the cause of cholera in London in the middle of the last century, and in other similar circumstances it has been accepted as satisfactory There is no reason for assuming that it is not completely trustworthy when applied by Dr. HAMER to prove the existence of a new method by which typhoid fever can be spread. We note that Mr. SHIRLEY MURPHY in his prefatory remarks has submitted Dr. HAMER'S report to a definite arithmetical test. He has taken a fixed period for the statement of the proportionate incidence of the disease upon the two populations we have mentioned and has thus brought out clearly the vast differences between the liability of those two populations to be attacked. The reader of the report will observe that, setting aside the few cases which Dr. HAMER had, for reasons stated in his report, not regarded as belonging to the "special outbreak," the only persons who were attacked were the fish eaters.

The circumstances of the Lambeth outbreak differ somewhat from those of the Southwark one, but this appears to be explicable on the ground that the population was less homogeneous, and hence the distribution of the cases was less compact than in Southwark. It is, however, noteworthy that the disease was limited to fried-fish eaters. In Kensal Town the conclusion is less positive, and perhaps nothing stronger can be said in support of the fish hypothesis in these cases than that it affords a possible explanation of them. We observe that neither Dr. HAMER nor Mr. SHIRLEY MURPHY is disposed to lay more stress upon the hypothesis than this. Now that attention has been directly drawn to this subject it is to be hoped that medical officers of health will bear in mind Dr. HAMER'S conclusions whenever they are concerned with outbreaks of typhoid fever or cholera for which other explanation is not forthcoming. It will be recollected that in 1893 certain persons, attacked with choleraic symptoms in London, had eaten fish received from the east coast. Dr. Hamer's report will serve to direct further attention to this question and it may be that a more intimate relationship between fish-eating and choleraic disease will be later established. The suggestion of this relationship undoubtedly demands that inquiry should be directed in ascertaining the extent to which frying or other culinary treatment destroys organisms in the fish. This, as Mr. Shirley Murphy points out, is matter for experiment. It is probable that the surface of the fish and material with which the fish is cooked are sterilised by cooking, but even in respect of this there is no certainty.

The Registrar-General's Annual Report.

The Registrar-General's sixty-second annual report has recently been published as a blue-book. It relates to the year 1899, and, like its predecessors, it is a highly important and interesting document; so much so, indeed, that we cannot forbear expressing regret that its preparation should have taken more than a year and a quarter after the close of the period to which it refers. The populations used throughout the book are avowedly estimated on the hypothesis that the rate of increase since 1891 has been the same as it is known to have been during the previous inter-censal period. At this distance, however, from the 1891 census it is very questionable whether population estimates so obtained are generally to be relied on; and we had almost expressed a wish that as the new census has already been taken the revised figures could have been used in calculating the rates of marriage, birth, and death for the present report. This, however, would have still further delayed the production of the report and to that extent would have diminished the value of the information it contains.

The continued prosperity of the country is attested by the marriage-rate, which in 1899 was higher than in any year since 1876, the rate having steadily increased to its present level ever since the year 1893. The birth-rate in 1899 was only 29·3 per 1000 and was the lowest on record, being below the mean rate in the previous 10 years by 1·0 per 1000. The death-rate was 18·3 per 1000 and was slightly below the decennial average rate. The death-rates for the several counties are given in the report. It must, however, be borne in mind that, inasmuch as those rates are based on purely provisional estimates of population, inferences from them are likely to need modification after the estimates have been revised on the basis of the 1901 census. In discussing the question of infantile mortality we are on firmer ground, and as in this case we are able to eliminate the errors inseparable from estimates of population the rates may be accepted as fairly trustworthy. In the year 1899 the proportion of deaths of infants under one year of age to registered births was 163 per 1000, which is somewhat higher than the mean proportion in the previous 10 years. In registration counties infantile mortality ranged from 106 in Rutlandshire and 108 in Herefordshire, to 186 in South Wales and 191 in Lancashire.

Among common infectious diseases scarlet fever, measles, and whooping-cough were much less fatal in 1899 than the average, the disease last mentioned showing a lower fatality than in any previous year on record. Diphtheria and diarrhœa, however, were more fatal than usual, whilst the mortality from enteric fever in 1899 has only once been exceeded in any year since 1884. The section of this report which deals with the local incidence of enteric fever is very complete and gives evidence of thoughtful preparation. In view of the well-known connexion between insanitary conditions and the prevalence of that disease we may be certain that this portion of the report will receive the consideration of the Local Government Board. The continued increase of diphtheria in recent years is once more adverted to in the present report, more than 10,000 deaths having been caused by it in the year under notice. The local incidence of this disease is here specially considered, and a table is given showing the mortality to which it gives rise in the several counties of England and Wales. In the year 1899 the mortality from diphtheria and croup did not exceed 98 per million of the population in Oxfordshire and 110 per million in Cornwall, whilst it amounted to 658 per million in Monmouthshire, 703 per million in Leicestershire, and 837 per million in South Wales. During the earlier years of life this disease is enormously more fatal than at subsequent ages, as many as 64 per cent. of the total deaths being those of children under the age of five years. In proportion to population the deaths from diarrhœal diseases were more numerous in 1899 than in any year since 1893. In addition to 31,000 deaths certified as from diarrhœa, more than 19,000 deaths were referred to enteritis or gastro-enteritis. Etiologically, all the infantile deaths referred to so called "gastro-enteritis" and a large share of those referred to "enteritis" should, doubtless, be considered as cases of epidemic diarrhœa. The fact that the age incidence of these maladies closely corresponds with that of epidemic diarrhœa strongly supports this view. It is much to be desired that in certifying deaths from epidemic diarrhœa medical practitioners should adopt the recommendation of the Royal College of Physicians of London, invariably using this term, or the suggested alternatives "epidemic enteritis" or "zymotic enteritis," and discontinuing the use of such terms as "gastro-enteritis," "muco-enteritis," and "gastric catarrh."

Among constitutional diseases both cancer and diabetes showed in 1899 a fatality in excess of the average, but tuberculous diseases had not exacted so heavy a toll. From cancer the mortality among males was equal to a rate of 672 per million, and among females to a rate of 977 per million, both these rates being the highest on record Out of a total of 26,325 deaths from malignant disease 736 were attributed in the certificates to scirrhus, 1293 to epithelioma, and 1706 to sarcoma—the remainder, amounting to 86 per cent. of the whole, being referred to carcinoma or malignant disease simply, without further discrimination as to kind. The mortality from phthisis is still happily on the decline; as compared with the respective averages, the male rate in 1899 was lower by 5 per cent and the female rate by 12 per cent. In both sexes the reduction in mortality was greatest at ages below 35 years; at the higher ages either the reduction was small or else there was an actual increase as compared with the average. Tuberculous meningitis accounted for not fewer than 6449 deaths in the year under notice. Most of these deaths were those of infants; among male children this disease was responsible for a death-rate of 1326 per million living under five years of age, and among female children for a rate of 1046 per million. Both these rates are, however, below the average. The disproportionate liability of male children to tuberculous meningitis is remarkable, male children under five years of age dying from this disease faster than female children by no less than 20 per cent.

Having regard to the remarks which we have recently felt called upon to make on the subject of death certification we are pleased to note that the resources of the General Register Office are being utilised with the object of ascertaining the extent to which the law is being evaded. We have repeatedly pointed out that although, taking England and Wales as a whole, the proportion of deaths uncertified by medical men does not exceed 2 per cent., nevertheless there are many districts (Spennymoor in Durham, for example) where the proportion of uncertified deaths is so high as to constitute a public scandal. In the report before us we are glad to find a table showing the registration districts in which the highest proportions of uncertified deaths occur. From this we find that in the year 1899 there were 55 districts which showed in every case a percentage of uncertified deaths amounting to more than double, and in one instance to more than nine times, the average proportion in England and Wales generally.

The Motor-Car Exhibition.

AN excellent insight into the progress of the motor-car and of its industry could be gained at the Royal Agricultural Hall this week (May 4th to 11th) on the occasion of the motor-car exhibition held there under the auspices of the Auto-mobile Club. It must be admitted, we think, that although advances in the structure of the motor-car are announced day by day and there is little doubt that the actually practicable motor will at length be realised, yet in the main progress is slow. Attention appears to be directed equally to electricity, steam, and petroleum as the motive power. Undoubtedly "petrol" is the favourite source of energy, while for many practical purposes, at any rate for the present, electricity is inadmissible. Some excellent motor-cars are now being made, however, which are driven by steam, and not the least advantages of these cars are that they are much less noisy than the petroleum-driven car, there is decidedly less vibration, and they are free from unpleasant smell. Apparently steam motors admit also of a greater simplicity and neatness of design than does the petroleum motor. But the requirements of a really useful motor are somewhat exacting. One important requirement (as, for example, in the case of the medical man) is that it should be ready for use without much preparation. The electric car requires practically no preliminary attention, the petrol-car requires some attention before a start can be made, while the steam car necessarily involves a good deal of time before it can be started. The steam-car, however, is evidently an increasing favourite, although by far the majority of cars are driven by petroleum. While it is true to some extent that petroleum is a manageable force, yet it is only so by virtue of the fact that it forms an explosive mixture with air. The petroleum must be uniformly vapourised and the resulting vapour mixed with air and the resulting mixture ignited before the energy of the petroleum is obtained as a propelling force. All this means an infinite amount of control at various points in the structure of the motor. Steam, on the other hand, is more easily under control because it is an expansive force, petroleum giving, so to speak, a series of jerks from results of explosions instead of a steady elastic pressure Until a way is found of storing electricity on a better plan than is at present available—that is, by the use of very weighty accumulators the capacity of which is necessarily limited—electricity cannot become a practical source of propulsion for the motor-car. At most not more than a 30 to 40 mile charge of battery power can be carried and this means a great weight, and then there is the inconvenience of the ever-present doubt as to whether the charge will serve, and there may be no re-charging station within reach. Sooner or later, however, the motor-car is sure to become a simpler and handier means of propulsion and more adapted for common every-day purposes than it is at the present time. The enormous attention that is being directed by a large and highly skilled body of engineering men towards the improvements of the motor-car is practically certain to be crowned with success in the near future. This reflection doubtless restrains many from possessing a motor-car, for rapid improvements may come at any moment. As it is, the improvements that take place every year are certainly noteworthy, all tending to the evolution at last of a really satisfactory motor-car. The relative merits of the different kinds of motors could easily be discussed at this exhibition, and a spacious arena was provided in which trial trips could be made. The hall was well-nigh intolerable, however, from the nauseating smell of escaped and partially burnt "petrol." One satisfactory feature of the exhibition was the fact that many of the improvements are due to English skill and ingenuity and a great many of the motors were entirely British made. Another point worth mentioning also is that the prices of the motor-car are evidently being gradually reduced; they are certainly much lower in price than in previous years, a really useful motor-car with accommodation for two persons costing now not more than 150 guineas The exhibition was of the most encouraging kind and undoubtedly teaches that amongst the industries of this country motor-car manufacture will have a very important place, serving to maintain a brisk demand for steel and a large field for foundry labour. The growth of the industry in the Coventry district and in many other provincial towns also is already very great, and there is little doubt that as the motor-car is further improved so *pari passu* the industry will expand. The time is sure to come when the production of motor-cars will be as large and as popular as was the case with cycles some few years ago. There is a peculiar and special interest therefore connected with the annual exhibition of the motor-car industry.

Annotations.

"Ne quid nimis."

THE LATE HONOURS GAZETTE.

THE *Army and Navy Gazette* of May 4th, referring to our remarks which "as in duty bound commented rather severely on the omission of the name of the Director-General of the Army Medical Service from the Honours *Gazette*," thinks that THE LANCET went a little too far in treating the honours conferred on Sir H. Brackenbury and Sir C. Mansfield Clarke as Director-General of Ordnance and Quartermaster-General at home as accentuating the omission of the name of Surgeon-General J. Jameson from the list. Our service contemporary adds: "How it can be supposed that the Army Medical Service must be unpopular in the eyes of its officers and of the profession on account of the omission is beyond our comprehension. It surely is not 'ignoring the Director-General' to give the G.C.B. to these two senior officers?" Admitting the force and truth of the remarks which follow in the article from which we are quoting about the relative value and importance which the world attaches to the work of its soldiers and sailors as compared with that of its physicians and surgeons we have nevertheless to confess that they seem to us wide of the mark. As a matter of fact, our comments simply stated the opinion which was generally entertained and had been freely expressed. That the Director-General of Ordnance and the Quartermaster-General thoroughly deserved their G.C.B.'s we never questioned and do not doubt, nor did it ever enter our minds to conceive that the Director-General of the Army Medical Service would have had that particular honour conferred upon him. Our point was that while Sir Henry Brackenbury and Sir C. Mansfield Clarke had been selected for reward in recognition of the services which they had performed in this country during the present war the name of the head of another department in this country, that of the Medical Service, on whom the war must have entailed an immense amount of labour and responsibility, was altogether omitted from the *Gazette*. The circumstance surely does tend to make the name of that official more conspicuous by its absence in the list than it would otherwise have been, and it is natural, indeed unavoidable, to notice and to seek for an explanation of such an occurrence. That was our point, and we are glad to see that the *Broad Arrow* looks at the matter with the same eye as ourselves.

THE EDINBURGH UNIVERSITY CLUB: LORD LISTER ON MEDICAL EXAMINATIONS.

THE Edinburgh University Club held a dinner at the Holborn Restaurant on May 1st. Lord Lister occupied the chair as President of the club, and he was supported by, among others, Sir James Reid, Lord Justice Stirling, Dr. Ferrier, Dr. Farquharson, M.P., and Sir Thomas Barlow. The company was large and everything went to show that the club is in a satisfactory state despite the great losses, very feelingly alluded to by the President, in recent months of two important members—the late Dr. J. B. Potter and the late secretary, Dr. Leslie Ogilvie. The music of the evening was supplied by Mr. William Nicholl who was frequently encored. In responding to the toast of "The Naval and Military Forces," proposed by Dr. Farquharson, Deputy Surgeon-General W. G. Don vindicated the military services, dwelling much on the actually new and unprecedented conditions of the war in South Africa. The feature of the evening was the speech by Lord Lister, revealing, as many previous speeches have done, his affection for Edinburgh and his gratitude for the influence of the Edinburgh University School, and especially of Mr. Syme's practice and character, on his mind. Lord Lister went to Edinburgh as Mr. Syme's house surgeon. Though, he said, he was not in the ordinary sense of the word a student of the University he received lessons there which were as valuable as any in his student career, and this in spite of the absence of many advantages which now existed in the form of laboratories of all kinds and a new infirmary. Lord Lister made some significant remarks as to recent changes in the examination system of the University and in the remuneration of professors. Formerly the candidates for graduation were examined solely by their professors and Lord Lister boldly intimated that in his opinion if the choice lay between examination of the student by his own teachers and by strangers he would unhesitatingly prefer the former on the ground that the teacher was likely to be the best judge of the real merits and the real knowledge of the student. The teacher's presence, with the help of an assessor, was perhaps the best guarantee for the avoidance of undue leniency on the one hand and what was probably a more serious fault—undue severity—on the other hand; the more so considering the enormous range and number of subjects which no teacher could cover entirely. Lord Lister used to say that it was impossible to teach the whole subject of chemistry; now it was equally true to say that it was impossible to overtake the whole range of surgery in any practicable course All the teacher could do was to teach sound principles with such materials as he could command. To subject the student to the examination of perfect strangers was a grievous injustice, and the student was tempted to study by cram to meet the views of various possible examiners. Lord Lister criticised with some disapproval recent changes in the payment of professors, maintaining that it should vary in proportion to their work and fitness. Referring to the club itself he thought that it maintained its health and prestige. It was most valuable in reviving old friendships and originating new ones and in promoting reverence and affection for the *alma mater*. Dr. Ferrier, in proposing the health of the President, said that no man of medical science had attained such wide renown or seen in his lifetime the fruit of his labours to the same extent as had Lord Lister. None had had higher honours conferred upon him or had borne them with more modesty. Lord Lister was more than great—he was loved. He told an anecdote of his humanity. In prescribing the actual cautery for one of Dr. Ferrier's patients Lord Lister expressed regret for the pain that it would cause. The patient said that he could submit to any pain which Lord Lister thought fit to order. "We are all proud of him," Dr. Ferrier added, and the toast was drunk with musical honours.

LAUGHTER AND LONG LIFE.

IT may be that some enthusiastic and laborious German statistician has already accumulated figures bearing upon the question of length of life and its relation to the enjoyment thereof; if so, we are unacquainted with his results and yet have a very decided notion that people who enjoy life, cheerful people, are also those to whom longest life is given. Commonplace though this sounds, there is no truth more commonly ignored in actual every-day existence. "Oh, yes, of course, worry shortens life and the contented people live to be old," we are all ready to say, and yet how many people recognise the duty of cheerfulness? Most persons will declare that if a man is not naturally cheerful he cannot make himself so. Yet this is far from being the case and there is many a man who is at present a weary burden to his relatives, miserable through the carking care of some bodily ailment, perhaps, or some worldly misfortune, who, if he had grown up into the idea.

that to be cheerful under all circumstances was one of the first duties of life, might still see a pleasant enough world around him Thackeray truly remarked that the world is for each of us much as we show ourselves to the world If we face it with a cheery acceptance we find the world fairly full of cheerful people glad to see us If we snarl at it and abuse it we may be sure of abuse in return The discontented worries of a morose person may very likely shorten his days and the general justice of nature's arrangement provides that his early departure should entail no long regrets On the other hand, the man who can laugh keeps his health and his friends are glad to keep him To the perfectly healthy laughter comes often Too commonly, though, as childhood is left behind the habit fails, and a half smile is the best that visits the thought lined mouth of a modern man or woman People become more and more burdened with the accumulations of knowledge and with the weighing responsibilities of life, but they should still spare time to laugh Let them never forget, moreover, and let it be a medical man's practice to remind them that "a smile sits ever serene upon the face of Wisdom"

THE KING AND THE CORONERS

AMONG the deputations received by His Majesty the King on May 3rd at St James's Palace was one from the coroners of England The deputation, which consisted of Mr Sidney Hacker, coroner for Devon, Mr Henry John Robinson, coroner for Lancashire, Dr Danford Thomas, coroner for Central London and Central Middlesex, Dr Wynn Westcott, coroner for North East London, Mr Arthur Langham, the treasurer of the Coroners' Society, and Mr Walter Schröder, secretary of the London Coroners' Association, was most graciously received in the Throne Room The President, Mr Hacker, presented an illuminated address, congratulating His Majesty upon his accession to the throne and giving an assurance of the loyalty and devotion to the Crown which the coroners, as His Majesty's own personal officers, ever feel towards the sovereign Each of the gentlemen present was introduced to the King who made the following reply —

"I thank you for your loyal and dutiful address and for your expressions of attachment to my Throne and to my Consort and my Family I appreciate the cordial sympathy which you express with our own and the nation's grief at the loss of my beloved mother, and I am deeply gratified *by your assurances of faithful service* to the Crown in the ancient and honourable office which you hold"

A similar deputation was received by Her Majesty Queen Victoria in July, 1897, on the occasion of the Diamond Jubilee

A MILITANT BACTERIOLOGIST.

WE regret to announce the death, at the early age of 40 years, of Professor P Kohlstock, which occurred at Tientsin on April 15th in consequence of heart failure following upon an attack of enteric fever During Professor Robert Koch's sojourn in South Africa for the purpose of investigating and combating the rinderpest Dr Kohlstock was his first assistant and wrote all the more important despatches and reports bearing upon rinderpest In Germany, however, his name is associated with several other, by no means less important, scientific adventures; indeed, he may be said to have been an adventurer in the truest sense of the word, for at a very early period of his life he voluntarily joined Wissmann's column as a leading member of his personal staff and took a prominent part in suppressing a number of sudden insurrections of the Arabs So highly did he distinguish himself in this respect that soon afterwards he was directed by the German Government to organise and to conduct the sanitary service in its East African colonies He accomplished this task and remained there till 1890, when he returned to Berlin and began some special bacteriological studies under the superintendence of Professor Koch In the following year the Seminar für Orientalische Sprachen was founded in Berlin, and Dr Kohlstock for some years lectured there at intervals on tropical hygiene To his connexion as a teacher with this institute he mainly owed the title of Professor which was bestowed upon him by the German Government in 1898 Nor were his interest and his activity confined to the latter work alone, indeed, his subsequent appointment as a scientific adviser to the German Foreign Office in matters bearing upon tropical hygiene occupied a great deal of his time and brought him into public prominence, with the result that he was soon approached by several private colonial associations to accept a post similar in character to that which he held in connexion with the Foreign Office Circumstances, however, led him to refuse these lucrative overtures, but, on the other hand, it is stated that on more than one occasion he rendered valuable practical assistance in matters relating to colonial enterprise to the leading colonial companies in Germany His name, however, was still more before the German public during the great cholera epidemic of 1893 He was then called upon to undertake the control of some of the main seaports and he fulfilled this task with conspicuous ability His scientific and literary contributions are numerous, but they are almost entirely confined to the domain of bacteriological and clinical research in connexion with malaria and yellow fever One popular book, however, which he wrote some two or three years ago is likely to remain of permanent importance—namely, his "Aerztlicher Rathgeber für Ost-Afrika und andere Tropische Malaria Gegenden" (Medical Guide for East Africa and other Tropical Malarial Regions) Lastly, in conjunction with Professor Koch he originated the scheme for the establishment of the Deutsche Anstalt für Tropen Hygiene (German Institution for Tropical Hygiene) which was recently erected in Hamburg

THE ASSOCIATION OF OBESITY WITH NARCOLEPSY

DR PAUL SAINTON of Paris contributes to the *Revue Neurologique* of March 30th last a paper on the Association of Obesity with Narcolepsy and gives an outline of the treatment proposed The torpor or somnolence of the obese is a fact of common observation, but attacks of narcolepsy—i e, of irresistible sleep—are rarer Of two cases of narcolepsy and obesity recently recorded it was found that diabetes was present in one (Robin) and albuminuria in the other (Lamacq) The following case was entirely free from any such disease or disorder, the only physical condition associated with the narcolepsy being obesity The case was that of a man, aged 43 years, a musical composer His father was gouty and his mother was subject to arthritis and eczema There was marked obesity in the grandparents The patient was thin and delicate in childhood, with an innate dislike of physical exercise He led a very regular life, was a big feeder, and at the age of 17 or 18 years began to grow fat He ate heartily of starchy and saccharine foods and drank red wine, but was not given to taking liqueurs He was a good sleeper at first, but subsequently he began to suffer from insomnia towards early morning, waking three or four times after a short sleep of two or three hours One morning he got up at six o'clock; a few minutes later he felt suddenly and irresistibly sleepy and slept for two hours During the day similar attacks of sleep occurred, and on one occasion while writing he suddenly fell asleep pen in hand These "crises" of sleeping seldom lasted more than a few seconds or minutes Sometimes when out visiting and during conversation he would suddenly fall asleep One day while descending a staircase he was suddenly overcome by sleep and rolled down the steps, sustaining a severe bruise of the forehead. Alarmed by these symptoms he decided to diminish his food with the result that he became less fat and the attacks of sleep became less frequent. But he failed to keep up the dietetic *régime* and became fat again. Later, he tried taking thyroid tablets, but these he found he could not tolerate owing to the production of tachycardia lasting several days after taking them. The attacks of narcolepsy now became more frequent and he consulted Professor Debove. He was now very fat, easily tired on exertion, and suffering from intertrigo. The urine was free from albumin, sugar, or bile, and the percentage of urea was normal. He was put on a special diet of fresh fruits, green legumes, plenty of water and of weak tea, and a dose of 10 minims of tincture of aloes after meals daily. The soup which he was allowed to take had to be free from fat. He lost his excess of fat after this and his weight, which at one time was 235 pounds, was gradually reduced to 157 pounds. His intellectual and physical vigour gradually returned, he slept naturally, and no longer had attacks of narcolepsy. Dr Sainton points out that Lamacq regards narcolepsy as not caused solely by obesity, because in two of his cases he noticed the presence of albuminuria and of enlarged tonsils respectively. The symptoms in the present case, however—viz., the association of narcolepsy with obesity uncomplicated by other conditions—and the results of treatment show that a constitutional condition characterised by slowness of tissue metabolism underlies both. Dr. Sainton thinks that this underlying condition may be due to some form of auto-intoxication, the narcoleptic attacks being due to the toxæmia affecting the brain. Suitable diet and increase of metabolism contributed to the cure of both the obesity and the narcolepsy in the present case.

THE FESTIVAL DINNER OF THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE festival dinner of the Royal Hospital for Diseases of the Chest, organised by the energetic secretary, Mr. John Harrold, was a decided success inasmuch as it realised £5800 of the £10,000 required for the purposes of purchasing a freehold site for the hospital, of building and furnishing a nurses' home, and of carrying on the work of the hospital. The dinner was held on Monday, May 6th, under the chairmanship of Sir T. Andros de la Rue, Bart., chairman of the hospital, at the Whitehall Rooms of the Hôtel Métropole and there was a good attendance. The toast of "His Majesty the King," proposed by the Chairman, was enthusiastically received with musical honours and the toast of "Queen Alexandra, the Duke and Duchess of Cornwall and York, and other members of the Royal Family," also proposed by the Chairman, was cordially responded to. In proposing the toast of the evening, "Success to the Hospital," the Chairman reminded his hearers that the hospital was founded by the Duke of Kent in 1814 and also that it was the first hospital in Europe founded for the study and treatment of consumption. At the present time there were about 800 in-patients treated annually, while the attendances of out-patients exceeded 26,000 annually. The reliable income of the hospital from annual subscriptions was less than one-third of the expenditure, and consequently from time to time the management got into troubled waters. The Prince of Wales's Hospital Fund Committee and the medical staff of the hospital insisted upon the imperative necessity of providing a suitable home for nurses which would cost some £7000, and £3000 were required for the ordinary work of the hospital. He concluded by asking for liberal support on the part of the charitable public. It would indeed be a pity if the remaining £4200 were not soon subscribed. The toast list included "The President, Lord Rothschild," proposed by the Hon. Claude Hay, M.P.; "The Chairman and other members of the Council," proposed by Mr. A. Wedderburn, K.C., and responded to by the Rev. G. H. Perry, M.A.; "The Medical Staff and other Honorary Officers," proposed by Colonel Makins and responded to by Dr. Philip J. Hensley; and "The Chairman," proposed by Mr. S. Hope Morley. The proceedings of the evening were enlivened by vocal and instrumental music, Miss Daisy Harrold, daughter of the secretary, making her public début with a charming rendering of a pianoforte solo, "Carmen."

THE GENERAL MEDICAL COUNCIL.

SUMMONSES have been issued for the meeting of the General Medical Council on Tuesday, June 4th, at two o'clock. The Executive Committee will, as usual, meet on the day previous. One matter of vital importance to the Council must receive early discussion. On the last day of the last session the Special Finance Committee of the Council presented a report on the financial condition of the Council which it was decided to refer to an expert in finance. The members of the Council were divided into two camps. On the one side it was asserted that the financial condition was sound, the annual deficit being too small to cause the slightest anxiety; on the other it was contended that a very serious condition of affairs existed which urgently called for reform. The point is so vitally important that the truth will have to be made clear at the first opportunity.

QUEEN VICTORIA'S NURSES' ENDOWMENT FUND.

IN THE LANCET of April 20th, 1901, p. 1152, we called attention to the special appeal to the women of the Empire for further funds permanently to endow Queen Victoria's Institute for Jubilee Nurses. The following committee, with power to add to their number, have now been appointed with the object of carrying out this project:—The Duchess of Beaufort, the Duchess of Bedford, the Duchess of Marlborough, the Duchess of Portland, the Duchess of Westminster, the Marchioness of Lansdowne, the Marchioness of Londonderry, the Dowager Countess of Shrewsbury, the Countess of Derby, Helen, Countess of Radnor, the Countess of Lonsdale, the Countess of Selborne, the Countess Roberts, Lady Lucy Hicks-Beach, Lady Aline Beaumont, Lady Hilda Brodrick, Lady Sandhurst, Baroness Burdett-Coutts, the Lady Mayoress, and Mrs. Beerbohm Tree. At a meeting of this committee, presided over by the Marchioness of Londonderry, held on April 29th at Londonderry House, Park-lane, it was decided that the wives of the Lord Lieutenants and the mayoresses of the United Kingdom should be approached and invited to identify themselves with the movement and to coöperate with Lady Londonderry's committee in carrying it out. In order that all classes, both in town and county districts, might have the opportunity of participating in the "Women's Memorial to Queen Victoria," it was also resolved that a thorough organisation should be instituted throughout the entire country. For this purpose arrangements will be made to ensure collecting cards finding their way into every village and remote hamlet, thus affording to the humblest the opportunity of subscribing their mite to the work. The present income of this institute, which for 12 years has ministered to the poorest people in the kingdom, is totally inadequate to meet the expenses, and unless the funds are greatly increased it will be impossible to keep up even the present number of nurses. To justify the council in considering the Queen's work as fairly established some 2000 nurses will be required, and to raise the establishment to this number will necessitate great efforts on the part of those interested in the work of the institute. The committee desire it to be understood that whilst contributions from those who can afford to give generously will be [illegible] 'hey equally wish it to be known tha [illegible] less fortunately placed will be heartily welcomed. Ladies desirous of acting on county committees or assisting in any way are requested to forward their names and addresses to the Honorary Secretaries, Women's Memorial Fund, 64, Cannon-street, London, E.C., stating the district and county in which they are desirous of working.

THE ROYAL SOCIETY.

THE Council of the Royal Society have recommended as Fellows of the society Major Ronald Ross, I.M.S. (retired), director of the Liverpool School of Tropical Medicine, whose researches into the etiology of malaria have borne such brilliant fruit; Dr. C. J. Martin, Professor of Physiology in the University of Melbourne and an acknowledged authority on snake-poison; and Major Alfred W. Alcock, I.M.S., superintendent of the Museum at the Medical College of Calcutta, and well known for his researches in marine zoology.

DRUNKENNESS AND HEREDITY.

IT is now 18 months since the Society for the Study of Inebriety appointed a special committee to consider the relation of heredity to inebriety. The committee was composed of five physicians, two surgeons, a professor of bacteriology, an army surgeon, and five general medical practitioners. 18 months have been spent in investigation. The report of this committee has just been published and it is signed by nine of the 14 members, some of whom have made comments, while one has sent in an independent report. The reference to the committee was in these terms: to investigate the conditions under which the tendency to drunkenness is capable of transmission to offspring. It does not appear to be contended that inebriety in itself is hereditary but that a capacity or tendency to it *is* heritable. The report declares that the inebriety of an individual depends upon three conditions—the first being an *inborn* capacity for enjoying the sensations which alcohol produces, and the second and third being *acquired*—personal experience of the pleasures of alcohol and the increased delight which continued indulgence confers in the case of the inebriate. That one drunken generation often succeeds another suggests an hereditary taint. The committee adds that there is no evidence that acquired characters of any kind are heritable. This appears to have been a much-debated question. Popular opinion has taken for granted that the acquired characteristics of parents are likely to be inherited and, of course, "temperance reformers," well-meaning, but often ignorant and misguided, have not been slow to urge upon the public that each man's drinking is pretty sure to produce for him a generation of children who will become drunkards. If this be not true the temperance reformer (who is generally in favour of entire abstinence rather than of temperance) must bear a heavy responsibility for the vast amount of mental torture which he has inflicted on the moderate-drinking citizen. The last word of science, however, as declared by teachers of physiology, biology, and botany, is a very definite assertion that no instance of the hereditary transmission of an acquired characteristic has ever been demonstrated either in the animal or the vegetable kingdom. If this be a fact a man can only transmit to his son the hereditary taint with which he was born, and if a man having no inborn tendency to excess yet acquires drunken habits his progeny are in no more danger than are those of his neighbour, leaving out of consideration the effect of environment on youth. It is not denied that drunken parents who become thus mentally and physically weak are liable to have children who are degenerate—weak in body and feeble in mind; such persons, in fact, as under unpropitious circumstances tend to become paupers, criminals, epileptics, and drunkards. The point which is denied is that the drunkard's child has the specialised tendency to become inebriate rather than vicious in some other direction. It seems probable that the question of environment is of more importance after all than that of heredity, and a man of strong will is just as likely to exercise it in the gratification of his desires as in the contrary direction. If a man of powerful will finds that alcohol gives him pleasure he will take good care to repeat the experience. The habitual drinker is one to whom alcohol brings enjoyment, either as positive pleasure or cessation of pain, whereas the voluntary abstainer is one who from constitutional peculiarity finds little pleasure in alcoholic exhilaration. Alcohol weeds out from every race the individuals who most enjoy and indulge in it. The races of Southern Europe who have had the longest experience of alcoholic drinks are now more temperate than the British, the Scandinavians, and the Russians. The committee is of opinion that the continued abuse of alcohol tends to render a race less innately prone to inebriety than it would otherwise have been, this result being brought about by the elimination of the drunken unfit and the survival of those with a weak tendency to alcoholism.

THE MIDDLESEX HOSPITAL LODGE OF FREEMASONS.

THE consecration of the Middlesex Hospital Lodge, No. 2843, took place at Freemasons' Hall, London, W.C., on Tuesday, May 7th. The ceremony of consecration was conducted by V. W Bro. Edward Letchworth, P.G.D., Grand Secretary, assisted by other Grand Officers, amongst whom were W. Bro. Clement Godson, M.D., P.G.D. (as S.W.), W. Bro. Alfred Cooper, F R.C.S., P.G.D. (as J.W.), and W. Bro. Surgeon-Lieutenant-Colonel H. W. Kiallmark, P.G.D. (as I.G.), W. Bro. T. G A. Burns, M.A., M.R.C.S., was appointed the first Master of the Lodge, with Bro. William Duncan, M.D., F.R C S., as Senior Warden, and Bro. Frank J. Wethered, M.D., F R C.P., as Junior Warden. The other officers are as follows: R. W. Bro. the Earl of Lathom, Prov. Grand Master for East Lancashire, I.P.M., Bro. Henry Morris, F.R C S., treasurer; Bro. F. Clare Melhado, secretary; W. Bro. E. J. Humphery, P.G.S., D. of C., Bro. A G. R. Foulerton, F.R C S., S.D., Bro. F. P. Wightwick, M D., J.D., W. Bro. C. Vincent Cotterell, I.G., W. Bro. Wilhelm Ganz, P.G.O., organist; and Bro. R. A. Young, M.D., steward. The Worshipful Master, in replying at the banquet to the toast of his health, remarked that the Middlesex Hospital Lodge was the fifth lodge founded in connexion with medicine in London, the others being the Æsculapius Lodge (which is a general medical lodge), the Rahere Lodge (St. Bartholomew's Hospital), the Sancta Maria Lodge (St. Mary's Hospital), and the Cavendish Lodge (West London Hospital). He also stated that he understood that three other great London hospitals were taking active steps for the foundation of Masonic lodges. About 70 brethren were present, including a large number of guests, W Bro. R. J. Reece, M.D., P.M. of the Rahere Lodge, and W. Bro. L. Bidwell, F.R.C.S., W.M. of the Cavendish Lodge, responding to the toast of "The Visitors." The Middlesex Hospital Lodge has started upon its Masonic career under most promising and pleasant auspices, and we venture to prophesy for it a success not less than that which has attended the other Masonic lodges attached to metropolitan hospitals. The good work done in the world's behalf by hospitals is known to everyone, and the good work done by Freemasonry, however jealously its mysteries may be guarded, is no secret, for public witness is borne to this fact by its magnificent charities—the schools for girls and for boys who are children of Masons and the Benevolent Institution for Aged Freemasons and Widows of Freemasons. Long may such a happy union of charity's forces as is evidenced by a hospital Masonic lodge flourish. The pleasure of the post-prandial proceedings was enhanced by an admirable selection of music by the "Westminster Singers" under the direction of Bro. Ganz.

SUPERVISION OF THE CRIMINAL INSANE IN THE PAST CENTURY.

IN the *Journal of Mental Science* for April Mr. Richard Brayn, superintendent of the State Criminal Lunatic Asylum, Broadmoor, deals with the important matter of the State supervision of criminal lunatics, and sketches the progress made with respect to their care in the course of the past century. Previously to the year 1800 no special provision was made for criminal lunatics; they were either dealt with as ordinary lunatics or were committed to prison and punished for their offences. The result of this was that "many of the bridewells were crowded and offensive because the rooms designed for prisoners were occupied by lunatics";[1] and, on the other hand, it was stated by the Attorney-General[2] that "persons who had committed the most shocking acts, and been acquitted on the grounds of being deranged in their intellects, had been allowed to go at large and again commit similar atrocities." In July, 1800, an "Act for the Safe Custody of Insane Persons charged with Offences" was passed. This is the oldest of the statutes relating to criminal lunatics and was the direct outcome of the trial of Hadfield for attempting the life of George III. The appointment of a Select Committee on Criminal and Pauper Lunatics in 1807 was the next step of importance. This committee recommended "that a building should be erected for the separate confinement of all persons detained under the above-mentioned Act ...... for offences committed during a state of insanity." Nothing was done, however, till 1814, when wards for the accommodation of 60 criminal lunatics were constructed in connexion with Bethlem Hospital; but a few years later it was found necessary to double the accommodation, and shortly afterwards further provision was required. In 1849 an arrangement was made whereby accommodation for criminal lunatics was obtained at Fisherton House and at the Camberwell and Dumfries lunatic asylums. The wards provided at Bethlem Hospital and Fisherton House soon became filled, and it was at last decided to build a special asylum for criminal lunatics, and in 1856 Broadmoor was selected for the erection of such an institution. In 1860 an Act of Parliament commonly known as the Broadmoor Act was passed, which made the necessary provisions for the government of such an institution, and for its annual inspection by the Commissioners in Lunacy, and in 1863 the Broadmoor Asylum for Criminal Lunatics was opened. Originally constructed to accommodate 400 male and 100 female patients, it has since then been altered and enlarged until now (1900) it has accommodation for 480 males and 187 females. In 1883 an Act called the "Trial of Lunatics Act" was passed. A further Act to consolidate and amend the Acts relating to criminal lunatics was passed in 1884. This Act makes provision for the certification and detention of insane prisoners as criminal lunatics, and is the statute which mainly governs the practice and method of procedure in dealing with criminal lunatics in asylums. The treatment of patients in Broadmoor Asylum is, says Mr. Brayn, based on the same principles as that of other asylums, excepting that in consequence of the dangerous and violent propensities of many of the patients, stricter supervision and a larger staff of attendants are required. From statistical tables compiled by Mr. Brayn it appears that 83·3 per cent. of the total population of the asylum were cases of homicide and homicidal attempts.

THE TREATMENT OF THREAD-WORMS.

IN our issue of April 20th there appeared a letter from a correspondent asking for some hints as to the treatment of thread-worms. In THE LANCET of April 27th another correspondent replied advising the use of copaiba given by the mouth. We have also received a letter from a non-medical correspondent who says that both he himself and a child, aged 10 years, were formerly greatly troubled with these pests. Our correspondent tried (doubtless under medical advice) many remedies but without success, until at last he took to having all drinking-water boiled, since when neither he himself nor the child has been troubled. The treatment usually recommended is that of enemata of solution of common salt, of solution of perchloride of iron, or of infusion of quassia together with a purgative. As, however, the main habitat of the worm is in the cæcum and not in the rectum it is obvious that rectal injections will generally fail to dislodge the main body of the parasites. Cobbold used to recommend aloes and assafœtida for adult patients and for young children small doses of perchloride of iron together with a saline purgative. But in no disease is the principle of *obsta principiis* more to be remembered than in cases where a patient is infested with oxyurides. Water should be boiled, though this is not the usual medium of infection, for the ova quickly die in water, and uncooked vegetables or fruit should be washed before being eaten. But in most cases the process of infection is a sort of vicious circle—namely, by the hands of the sufferer himself, the ova being conveyed to the hands by scratching and thence to the mouth again. Strict personal cleanliness is therefore of the highest importance and the nails should be kept as short as possible.

THE PRODUCTION OF BACTERIAL DISEASE IN RATS AND MICE.

IN April, 1900, Professor Danysz of Paris published in the *Annales de l'Institut Pasteur* an account of a micro-organism pathogenic to rats, whether given in their food or by subcutaneous injection, and presenting some resemblance to Loffler's "mouse typhus" bacillus and to the bacterium coli. Bacilli which had been once passed through an animal killed rats in from seven to 12 days, but by successive passages through animals their virulence diminished and finally disappeared altogether. Professor Danysz was very successful in experiments which he made on a large scale for the destruction of rats in drains by this means, for the dead rats were eaten by the others and thus the disease was spread. With a view to test the applicability of the method for the destruction of rats in time of plague Dr. J. Kister and Dr. P. Kottgen of the Public Health Institute in Hamburg have made a number of observations which are published in the *Deutsche Medicinische Wochenschrift* of May 2nd. They found, like Professor Danysz, that the virulence of the bacillus for rats diminishes with successive passages through the animal organism, and after about 10 passages it no longer causes death. For their experiments they grew pure cultures from the heart-blood of dead animals on agar plates. The weight of an agar plate stroke culture mass of 24 hours' growth was about nine milligrammes, and a rat was, on an average, given bread soaked in fluid containing one of these. These rats, after they had eaten the whole of the bread, were put in a cage with a large number of healthy rats. The latter did not fall ill if the infected rats as they died were immediately removed from the cage, but if food were withheld, so that the dead rats were eaten by the others, the disease immediately spread and the rats infected from the dead bodies died in about the same time as those which were fed on the bread to which the cultures were added. Fowls, cats, dogs, and guinea-pigs to which the bacilli were administered suffered from no symptoms of illness whatever. The rats killed in this way never showed the swellings of the lymph glands or the hæmorrhages into the internal organs and into the subcutaneous connective tissue which are almost invariably found in rats that have died from plague

THE ANNUAL DINNER OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE annual dinner of the West London Medico-Chirurgical Society was held on Wednesday last, May 8th, at Frascati's Restaurant The President, Dr. F. F. Schacht, was in the chair, and the list of speakers included, among others, the names of Sir Richard Douglas Powell, Dr F. W. Pavy, Mr. Howard Marsh, Mr. C. B. Keetley, and Dr. Seymour Taylor. About 130 members and guests attended. Dr. Pavy, President of the Royal Medical and Chirurgical Society, in replying to the toast of "Kindred Societies," spoke eloquently upon the extension of medical knowledge and science which had taken place during the last few years, pointing out that this had led to the formation of many medical societies founded for the consideration of all the various points of interest in the different branches of medicine and surgery. The enormous increase in the population of London alone had created districts far away from the centre where the older societies had their home and younger societies had been constituted to fill the want of a local centre of discussion. The West London Medico-Chirurgical Society was formed in this manner, and though the older societies could not help feeling that these vigorous saplings drew a certain amount of sap from the parent stem, the feeling towards them was one of congratulation, for it was recognised that they had the same object as their seniors—viz , the extension and diffusion of medical knowledge for the good of humanity

THE HEALTH PROSPECTS OF HAVANA UNDER THE UNITED STATES GOVERNMENT.

WE have received a copy of a very interesting communication from the chief sanitary officer in Havana, Cuba, to the Adjutant-General, Department of Cuba, regarding the vital statistics of Havana for the month of March last. The population numbers 253,333 and Major W. C Gorgas, Surgeon in the United States Army, the chief sanitary officer, invites the attention of the major-general commanding to the continued excellent sanitary condition of the city as shown by the general death rate of 26 28 per 1000 which is considerably lower than that of any March since 1889—the lowest previous rate for the preceding 11 years being that of 1893 when it was 27 60; the highest that of 1898, the last year of Spanish occupation, when it stood at 78 00 It will be seen from this that there has been a steady decrease since the American occupation and that Havana will now compare favourably with many other of the larger cities of the world. As regards yellow fever the report is especially good It shows four cases and one death The only two years since 1889 showing as small a number of deaths as this were 1892 and 1899, when there was one death in March for each of these years In 1900 during March there were 11 cases and four deaths "As a matter of fact we have had only one case of yellow fever in Havana since March 1st, and since March 23rd the city of Havana has been entirely free from that disease This is the first time this has occurred since June, 1899. There were two occasions in 1900 when we went for a few days with no fever, but none since the time mentioned that we have been free from fever as long as at the present I feel very much encouraged at the prospects for the summer." The chief sanitary officer thinks that the present freedom from fever is in part due to the systematic and extensive way in which the mosquitoes have been killed. He states that he has the greatest hopes of destroying the foci as they appear by systematically killing the mosquitoes over a large area around each focus as it occurs. He is inclined to think that they have been free from fever for a longer time than has ever occurred in Havana before With regard to small-pox the report is equally satisfactory. Not a single case has occurred in Havana since August, 1900 These two diseases, yellow fever and small-pox, have been looked upon as being endemic in Havana; consequently the present state of affairs is particularly worthy of remark. A large amount of sanitary work is being done and bacteriological examinations are being instituted.

NICOTINE AND FUSEL OIL.

MODERN researches are distinctly tending to show that neither are the poisonous effects of unlimited tobacco-smoking due to nicotine nor are the toxic consequences of excessive whisky drinking due to fusel oil. Whisky certainly does contain fusel oil and tobacco contains nicotine, but while the fusel oil directly reaches the system it is practically certain that the nicotine of tobacco does not occur as such, at any rate to any extent, in the smoke. By far the greater portion of the nicotine in tobacco—and as we have shown the amount of nicotine in Virginia tobacco does not often exceed 1 per cent , although there is a popular idea that the quantity of nicotine is much more than this—is destroyed by the combustion. New products, however, are formed, consisting of tobacco tar-oils which are undoubtedly poisonous The foul smell of a well-used pipe is due to these oils, in which analysis has shown but a trifling quantity of nicotine The composition of these oils indicates that they are very closely related to nicotine, and their chief constituent is pyridine, and it and its "relatives" are responsible for the violent headache, trembling, and giddiness following excessive smoking. The degree of toxicity of the smoke, however, probably depends largely upon the completeness of the combustion The combustion of the cigarette is probably more complete than that of the tobacco in a pipe or of the uncut leaf of a cigar. But the pipe serves as a condenser, the condensed products not reaching the mouth The filthy fluid accumulating in a pipe is very poisonous. A good deal of condensation must take place in the cigar and, moreover, the products reach the mouth and are absorbed. According to this we should place in the order of injuriousness, beginning with the worst first, the cigar, the pipe, and the cigarette The experience of juvenile smokers or beginners would seem to bear out this classification. With the schoolboy the first step to smoking is the cigarette, then the pipe, and later he is tempted to try the cigar Much in the same way that nicotine was credited with being the poisonous agent in smoking, so fusel oil has been looked upon as the constituent producing the train of symptoms (chiefly headache) following a free potation of not too good whisky It is now shown that, comparatively speaking at any rate, fusel oil is not the injurious constituent of whisky It is rather the aldehydes, the partly oxidised alcohols in whisky, which are mischievous, and the chief amongst these is furfural Old matured whisky is free from furfural, while freshly made or unmatured spirit contains a marked amount of this constituent, the source of the throbbing headache of the heavy drinker. In the light of these interesting observations it is apparently no longer correct to speak of fusel oil in whisky as the toxic body which it is desirable to eliminate or of nicotine as the poisonous constituent of tobacco smoke. In the former case it should be furfural and in the latter case pyridine and its congeners.

THE METROPOLITAN ASYLUMS BOARD.

THE resignation by Sir Edwin Galsworthy of the office of chairman is an event in the history of the Metropolitan Asylums Board. He has been a manager of the Board for 33 years and chairman for a period of 20 years. Opinions will vary as to the policy of the Board in developing the system of wholesale admission of all infectious cases to the hospitals of the Board without discrimination as to the social position and means of patients—a system which is said to cost £700,000 a year instead of £4000 which was the expenditure when Sir Edwin Galsworthy became a member. According to a statement by Mr. Elliott, one of the representatives for Islington on the Metropolitan Asylums Board, it is one of the most expensive boards in the kingdom. Originally intended for the poor, its hospitals are open to all comers, and patients are visited, according to Mr. Elliott, by "friends who come in a carriage-and-pair." This statement may be inaccurate or misleading, but it is certainly true that the doors of its hospitals are open to patients of all classes, and to classes for which these hospitals were never intended. And the development of this system certainly coincides with Sir Edwin Galsworthy's chairmanship. He has nevertheless been an able chairman who has displayed such a power of work, and such tact and ability, as have induced the managers to re-elect him to the chair for 20 years. We shall not choose this moment to be critical or to press the suggestion that the time is ripe for investigating the effect of the hospitals on infectious diseases and on the limitation of their spread, the more so as we fully recognise with the managers the great work which has been done and the great qualities which have been displayed by Sir Edwin Galsworthy, and we are ready to admit that the grave responsibility for the wholesale gratuitous treatment of disease in persons who are not paupers must rest ultimately not with him and his colleagues, but with Parliament and the Local Government Board which was intended to have some function in regulating the uses of these hospitals. The expenditure is part of that municipal expenditure which is grossly overlooked by Parliament and which is rapidly involving a debt that threatens to reach the proportions of the national debt.

A TELEGRAM from Sir W. F. Hely-Hutchinson, Governor of the Cape of Good Hope, states that for the week ending April 27th the total number of cases of plague admitted to hospital was 63; of this total 22 were Europeans, 35 were coloured, 5 were Malay, and 1 was a native. The deaths numbered 32—9 European, 18 coloured, and 5 Malay. The number of cases admitted up to midnight on April 27th was as follows: European, 135; coloured, 226; Malay, 26; Indian, 5; Chinese, 1; natives, 126; total, 519. Total deaths: Europeans, 41; coloured, 102; Malay, 20; Indian, 5; natives, 49; total, 217. A private in the Royal Engineers had been attacked. Among persons under naval and military control the total up to April 27th reached 43. No further cases have been discovered at Port Elizabeth. A case having all the symptoms of plague has been reported from Mafeking.

THE London Companies of the Volunteer Medical Corps are giving a dinner to welcome home the members of the corps returning from active service in South Africa. The dinner will take place at the Holborn Restaurant on Saturday next, May 18th, and communications from those intending to be present should be made to the honorary secretary of the Officers' Mess, 51, Calthorpe-street, London, W.C.

THE annual dinner of the Indian Medical Service will be held at Prince's Restaurant on Thursday, June 13th, at 7.45 P.M., Surgeon-General R. Harvey, C.B., D.S.O., the Director-General, in the chair. Officers intending to be present should communicate as early as possible with the honorary secretary, Mr. P. J. Freyer, 46, Harley-street, London, W.

THE annual dinner of the Chelsea Clinical Society will be held on Thursday, May 23rd, at 7.45 P.M. in the Princes Room of the Criterion Restaurant. Further particulars may be obtained from the honorary secretary, Dr. Austin Cooper, 41, Sloane-square, London, S.W.

LORD LISTER and Sir William Broadbent attended the first sitting of the Commission of Inquiry at the National Hospital for the Paralysed and Epileptic, Queen-square, London, W.C., on May 4th. The commission have continued their sittings since last Saturday.

THE twenty-third annual congress of the American Rhinological Association will be held in the Dwight Hall of Yale University on May 27th, 28th, and 29th. Dr. H. L. Swain of Newhaven is the President of the Congress for the year.

WE are glad to be able to congratulate Sir Frederick Treves, C.B., upon his knighthood, the King having conferred upon him since our last issue the distinction of Knight Commander of the Royal Victorian Order.

THE annual dinner of the Pharmaceutical Society of Great Britain will be held at the Whitehall Rooms of the Hôtel Métropole on Tuesday, May 21st.

A SERIOUS epidemic of scarlet-fever, prevalent in Shoreditch and Bethnal Green, has been traced to an infected milk-supply.

MEDICAL NOTES ON THE LIFE OF EDWARD GIBBON, THE HISTORIAN.

By WILLIAM H. HORROCKS, F.R.C.S. ENG.,
HONORARY SURGEON, BRADFORD INFIRMARY.

IN studying the life-history of an individual long since dead the account has frequently to be drawn from non-medical sources and is of necessity indefinite and in parts incomplete. It is of interest to trace the effects of health and physique in shaping the career.

Edward Gibbon was born on April 27th, 1737, of parents in a good social position. His father contested a county election in times when rival candidates showered bribes on their bibulous supporters. Edward Gibbon was the oldest of six children, but the other five died at an early age. So feeble was his constitution that in the baptism of his brothers his father's name was given to each succeeding child. Gibbon in his autobiography says that his mother's attention was somewhat diverted by her frequent pregnancies, by an exclusive passion for her husband, and by the dissipation of the world. The maternal office was fully supplied by his aunt who not only tended him with care but sought the medical aid of every practitioner from Sloane to Ward. As he had trouble with his sight the services of Chevalier Taylor, a well-known quack oculist, were called into request. So he passed a sickly childhood with frequently interrupted attempts at education. When he was 13 years of age he suffered from a strange nervous affection which alternately contracted his legs and produced, without any visible symptoms, the most excruciating pain. For this he was treated at Bath "by bathing and pumping." Writing to Lord Sheffield in later life he thus sums up his early history: "I was a puny child, neglected by my mother, starved by my nurse, and of whose being very little care or expectation was entertained; without the vigilance of my aunt I should have gone to my grave or imperfectly lived a crooked rickety monster, a burden to myself and others. It might be apprehended that I should continue through life an illiterate cripple, but as I approached my sixteenth year nature displayed in my favour her mysterious energies My constitution was fortified and fixed and my disorders, instead of growing with my growth and strengthening with my strength, most wonderfully vanished. I have never possessed nor abused the insolence of health, but since that time few persons have been more exempt from real or imaginary ills."

At 15 years of age Gibbon was admitted a gentleman commoner at Magdalen College, Oxford. His duties here were not arduous, for after paying his fees he was not further troubled by his tutors during his term of residence. No college lectures were delivered and the life of the professors was spent in hunting, dining, and discussing the politics of the day. Gibbon's naturally studious inclinations led him to read deeply in classics, to which he had ready access. His father, however, cut short his university career on hearing that his son had become converted to the Roman Catholic faith. He was withdrawn from Oxford and sent to Lausanne to be under the care of a Lutheran minister. Here Gibbon continued his student life under the guidance of an able teacher. "The desire of prolonging my time of study gradually confirmed the salutary habit of early rising to which I have always adhered. It is happy for my sight and my health that my temperate ardour has never induced me to trespass on the hours of the night." After three years at Lausanne he returned to England, where he lived until the death of his father. Gibbon then returned to Lausanne and began his great life-work, "The History of the Decline and Fall of the Roman Empire." This work was published in six quarto volumes between 1766 and 1787. Early in 1790 Gibbon had an attack of gout which began with acute pain in the foot and was followed by weakness in the knees, which kept him a prisoner for several months. The length of this attack may possibly be accounted for by the pipe of excellent port which his friend Lord Sheffield had sent him.

In 1791 Gibbon's health showed evident signs of failure. "Although he was inclined to represent his health as better than it really was his habitual dislike to motion appeared to increase. His inaptness to exercise confined him to the library or dining-room, and there he joined Mr. Frederick North in arguments against exercise in general. He ridiculed the unsettled and restless disposition that summer, the most uncomfortable of all seasons, generally gives to those who have free use of their limbs." In a letter to Lord Sheffield in November, 1793, Gibbon writes: "I must at length withdraw the veil before my state of health, tho' the naked truth may alarm you more than a fit of gout. Have you never observed through my inexpressibles a large prominency, which, as it was not at all painful and very little troublesome, I have strangely neglected for many years? But since my departure it has increased, is increasing, and ought to be diminished. Yesterday I sent for Farquhar, who is allowed to be a very skilful surgeon. After viewing and palping he very seriously desired to call in assistance, and has examined it again to-day with Mr. Olive, a surgeon of the first eminence. They both pronounce it a hydrocele (a collection of water) which must be let out by the operation of tapping, but from its magnitude and long neglect they think it a most extraordinary case and wish to have another surgeon, Dr. Baillie, present. If the business should go off smoothly, I shall be delivered of my burden (it is almost as big as a small child), and walk about in four or five days with a truss. But the medical gentlemen, who never speak quite plain, insinuate to me the possibility of an inflammation, of fever, &c." A few days afterwards Gibbon was tapped for the first time, four quarts of a transparent watery fluid being evacuated Neither fever nor inflammation ensued and the tumour was reduced to nearly half its size. The remaining part was a soft, irregular mass. He was about again in a few days, but the water collected very fast. The swelling was again tapped in a fortnight, this operation being more searching and painful than the first, but it eased and lightened him to a much greater degree. Three quarts of a similar fluid were discharged; "no inflammation; *a good night; permission to go out on the following* day, and to await the future measure of a radical cure."

On Dec. 23rd, 1793, his appetite began to fail; a considerable degree of fever now made its appearance. Inflammation arose from the weight and bulk of the tumour and water again collected very fast. The tumour became more distended and ulcers formed in many places. Remedies were applied to abate the inflammation but it was not thought proper to puncture the tumour a third time until Jan. 13th, 1794. He seemed much relieved by the evacuation. On the third day after the operation he complained much of his stomach and of a disposition to vomit. Soon after 9 P.M. he went to bed and took his opium draught; he became gradually weaker and died on the following day. At the post-mortem examination the following condition was found. The scrotum formed a large sac which descended almost to the knee. The skin covering it was ulcerated at several spots. The sac contained part of the colon and the whole of the omentum, which was much enlarged. The stomach was dragged down so that its orifice was near the pubes. "This," the writer says, "was probably the cause of death." On the omentum and intestine were small spots of livid colour. In the liver a great number of small tubercles were seen.

It is very evident from the account of the illness and examination that Gibbon died from septic infection. The first two tappings were satisfactory, but after the second tapping the skin of the scrotum sloughed and the third tapping infected the sac. This caused a localised peritonitis of the sac and its contents with secondary abscesses in the liver. From this description it appears that his disease was irreducible hernia with accumulation of fluid in the sac and not, as usually stated, hydrocele of the tunica vaginalis.

PROVISIONAL RETURNS OF THE CENSUS OF 1901.

WE are indebted to the Registrar-General for the tables at the end of the present article which give the first results of the recent English *census* The present list is limited to the metropolitan boroughs and the county boroughs of England and Wales It is based on the summary returns furnished by the local registrars, and accordingly must be regarded as provisional only, being subject to modification in detail when, in due course, the enumeration books have been received and scrutinised at the central office. The publication of census returns by instalments, whilst in some respects a desirable arrangement, is nevertheless likely to give rise to more or less dissatisfaction among the dwellers in those districts which are not included in the earliest lists. Others, again, will be impatient because a statement of the entire English population is not furnished at once. But a little consideration will show that the labour of accurately summarising and tabulating the populations of a vast number of small and highly complex areas is very considerable and is calculated to tax severely the energy and ingenuity of any staff; added to which we are officially informed that the local registrars were not instructed to transmit their summaries to the central office until April 27th at the earliest. We, therefore, are of opinion that credit is due to the authorities at Millbank for having prepared and published within ten days of the commencement of the work a *summary* which deals with the metropolis and with the whole of the more important towns of England and Wales.

Turning first to London, we find that on April 1st the administrative county contained 4,536,034 people, being an increase of more than 307,000 on the number enumerated 10 years ago. Estimated to the middle of the present year the population of the metropolis is 4,543,700 in round numbers, which is below the estimate based on the increase between the two previous censuses by more than 107,000. In the several metropolitan boroughs the movement of the population since the last census has been very unequal. In seven of the boroughs—namely, Bermondsey, Finsbury, Holborn, St. Marylebone, Shoreditch, and the Cities of London and Westminster—there has been a decrease in the population, whilst in the remainder of the metropolis the numbers have increased, the increase having been greatest in Wandsworth, Woolwich, and Lewisham. In the 67 provincial county boroughs there has been inequality in the movement of population quite as marked as that which has occurred in the metropolis. In a few of the older towns the population has remained almost stationary, and in others, such as Bath and Chester, there has been some slight decrease since 1891; but in the great manufacturing cities, such as Liverpool, Manchester, Birmingham, Leeds, and Sheffield, there have been increments of population in the last decade ranging from 40,000 to 50,000, and even 60,000.

It is chiefly in relation to vital statistics that the returns of the census are interesting and serviceable to our profession. Students of preventive medicine generally, and especially those holding public health appointments, have to rely entirely on these returns for the correction of the estimates of population on which local rates of sickness and mortality are computed, and thus a test is provided by which the results of sanitary improvements can be judged. From this point of view it will be useful to compare the estimates of population based on the recent enumeration with those calculated beforehand, on the theory that the rate of increase or of decrease in the last intercensal period has been maintained since 1891. Taking the 33 great towns of the Registrar-General we note that the populations of 24 of them, including London, had been over-estimated, in several instances very seriously; that in five cases they had been under-estimated; and that in four cases only did the previous estimate agree closely with the results of the recent census.

Under these circumstances it is clear that for purposes of accurate vital statistics an enumeration of the people ought to be taken more frequently than once in ten years, and we hope that when the quinquennial London census of 1906 comes to be provided for arrangements will be made to extend the provisions of the Metropolitan Act to the remainder of England and Wales.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1899.

FIRST NOTICE.

THESE reports are so ably drawn up and contain such an excellent *résumé* of the latest information and literature on the subjects of which they treat that we always welcome their appearance and regret that they are not better known to the profession generally than they seem to be. In this respect, however, they probably only share the fate of other Government documents drawn up with great labour and skill. The fact that these annual reports happen to deal largely with statistical data relating to the public health that obtained in India a year or two previous to the date of their publication probably has a deterrent effect on the readers of medical literature other than those directly interested in Indian affairs. All we can say is that it is unfortunate if this be so, for the reports, as we have said, contain a mass of valuable and carefully compiled scientific information regarding the etiology and pathology of a variety of diseases which is not to be elsewhere met with in such a compendious form. From an official standpoint the statistical data and the conclusions that may be deduced from them are invaluable to statesmen, to military authorities, and to others connected with the government and wellbeing of India, because many of these conclusions, having been derived from observations drawn from large numbers and repeated over a long series of years, may be regarded as very much in the light of natural laws. They must therefore be taken into practical account in considering any Indian policy or dealings with that country. They may be regarded, too, as the only available guides which we have for forming an estimate of what may be expected to occur in other climates of a tropical or sub-tropical kind. It would be a great mistake, however, to suppose that the value of these reports is circumscribed within these limits. It is their medical interest and value with which we are concerned and it is in these respects that we hope to show that they are not lacking.

Starting with the European army in India we may, in the first place, give a summary or bird's-eye view of the statistical results. The health of the European troops in 1899 was again much better than in the preceding year, the rate of invaliding only being greater than in the corresponding decennial ratio. The year on the whole was hot and dry, with deficient rainfall. To these meteorological conditions is attributed in the report the fact that the admission-rate, death-rate, and invaliding-rate from malarial fevers were much reduced. The total strength of the

European army in India was 67,697 in 1899. The chief causes of admission were venereal diseases and ague. The former caused 27 per cent. of the total sickness and ague 20 per cent. The chief causes of death were enteric fever and hepatic abscess. Enteric fever caused 40 per cent. of the total deaths and hepatic abscess 10 per cent. The causes of invaliding were numerous and need not be enumerated. A table is given of the comparative ratios of the different military commands. Bengal had the highest mortality from heat-stroke, tubercle of the lungs, and dysentery; the Punjab the highest rate from enteric fever, remittent fever, pneumonia, and other respiratory diseases; and Madras, which recorded the lowest mortality-rate but the highest constantly-sick and admission rates, had the highest death-rate from hepatic abscess. All the commands were more healthy than in 1898. Of the larger military stations Peshawar, Lucknow, Umballa, and Bangalore return the highest death-rates. There was only one case of cholera in the whole of the European army in India in 1899, and "never before in the records of this office," says the Sanitary Commissioner with the Government of India, "has so low a mortality appeared." There can, we think, be little doubt that the persistent efforts in carrying out sanitary improvements in all that concerns the European army in India have had a most favourable effect, for we no longer hear of the wide-spread epidemics and outbreaks of cholera in cantonments which were once so frequent. It is remarkable how little we still really know, however, of the conditions which give rise to the widespread prevalence of a disease with its epidemic intensity in one year, and its dormancy or almost complete disappearance during other years where the conditions, whether meteorological or otherwise, seem to be identical or nearly the same in both cases alike. The phenomenon is of too striking a character not to have attracted notice always, and its explanation was once vaguely relegated to an epidemic constitution of the year or season. Explain it as we may, it makes all the difference in India if it is, as recognised by the natives of that country, a cholera year or not—whether the land is to be devastated by disease, or, in spite of having numerous foci of infection apparently ready for its spread, it is to have complete or comparative immunity from it in epidemic extent and force.

The subject of fever in India is a very wide and ill-defined one owing to the different forms and varieties of fever not having been accurately differentiated from one another. With regard to cases of remittent fever, about the exact nature of which there apparently exists some doubt, we may say that at Shwebo the disease, often of a severe type, was in all cases contracted in the very malarious forests to the north-east of the station where the natives, towards the end of the rains, had been dying in numbers from that disease. Of 11 fatal cases 10 of the bodies were examined. In five no very definite lesions were discovered, and in the remaining five the lesions were of various kinds, but not characteristic or indicative of enteric fever At Barrackpore cases suspected of being enteric fever, but not reacting to Widal's test, were returned as remittent fever, but they did not respond to the exhibition of quinine. Of the cases of so-called "simple continued fever" some are forms of heat fever or various local and constitutional affections attended with febrile disturbance, some turn out to be enteric fever or of a malarial or influenzal nature, and some appear to be cases of mistaken diagnosis. Latterly it has been suspected that the form of fever known as "Malta fever" or "undulatory fever" prevails in India, and a number of such cases are being discovered both among Europeans and natives. But we are told that "the experience of the past should warn those in authority, while encouraging the research, to exercise a certain amount of reserve in the acceptance of at least the earlier results. After all, serum diagnosis is still in its infancy or just emerging therefrom."

We now come to the subject of enteric fever, about the literature of which the report, together with the preceding one for 1898, contains a large amount of admirably compiled and interesting information. Among other references, it largely lays under contribution the Goulstonian Lectures for 1900 by Dr. P. Horton-Smith as adding some recent and very valuable information about enteric fever from its scientific side The report quotes among the more general conclusions at which Dr. Horton-Smith has arrived those illustrative of the distribution of the typhoid bacillus to the most diverse organs throughout the body, showing that "any conception of the disease which regards it merely as affecting the alimentary canal only can no longer be maintained." (We may parenthetically remark here that the use of the term "enteric" in army medical nomenclature is consequently misleading and no longer warranted.) So far from considering it as an intestinal disease pure and simple, it should rather be looked upon as a modified form of septicæmia, for the bacilli always and in all cases pass into the blood and then into the various organs. For years past precautions have been taken as regards the intestinal discharges. But it is the subject of the urine in its relations to the enteric bacillus, since the discovery of the bacillus in that fluid during the later stages of the disease and sometimes for a very considerable time afterwards, that has of late engaged so much attention. The bacillus gives rise in the skin to the typical eruption and Fraenkel has been able to show the multiplication of the bacillus in some excised roseola spots kept under proper conditions and with proper precautions. In stained sections he was able to find little heaps of bacilli lying in the papillary portions of the cutis and to demonstrate thereby that the roseola is not merely a hyperæmia, but a local lesion caused by the bacillus. The Sanitary Commissioner with the Government of India quotes as interesting to sanitarians in India some remarks from an article in THE LANCET on the endemic fever of English towns,[1] with special reference to the report of the medical officer of health of Chichester. *Apropos* of the prolonged infectiousness through the urine, for example—which is on the whole more dangerous than the fæces in this respect—of persons apparently restored to health after an attack of enteric fever, and the power of the bacillus to resist the effect of desiccation it becomes easy to understand how bacilli eliminated from the body may pass into the atmosphere and subsequently give rise to disease by being carried in the form of dust. Whether it be in this way or by an actual growth of the bacillus in the soil outside the human body is a question which can be settled only in the future. The report then takes up and discusses a number of points connected with water, filters, chemical purifiers, and bacteriology, together with some questions of a medical and pathological kind. However interesting these may be we must not linger over them

The great practical point connected with the returns of enteric fever in the European army serving in India is the marked improvement that has taken place in 1899 and the way in which it is to be explained. In 1898 the disease caused 2375 admissions and 654 deaths, and in 1899 (the year under report) there were 1392 admissions and 348 deaths. The admission-rate fell from 36 9 to 20 6 and the death ratio from 10 17 to 5 14. From this it will be seen that there has been a very marked fall indeed in the number of cases and a still more marked diminution in the mortality—the latter, indeed, being less than it has been for the previous nine years. While we may congratulate ourselves on this fact we wish that we could equally congratulate ourselves on any assured belief that we were at last on the right road; that, as these results were the first-fruits of an application of modern methods of preventive medicine in India, so we had only to continue and to increase our efforts to ensure a progressive improvement in the future. The report does not, however, give us any assurance of the kind. It practically ascribes the change to two factors—first, that owing to the war in South Africa the influx of drafts from home was stopped during part of the year, and, secondly, that there was no field service going on in India during the year. Seeing that the liability to die from enteric fever during the first year of residence in India is far greater than in any subsequent year it follows that in proportion as the supply of this susceptible material is reduced or cut off will there be a corresponding reduction in the prevalence and amount of this fever. It is, as we know, a well established fact that enteric fever affects the young and recently-arrived soldier. Of 100 cases of enteric fever 43 will be in patients between the ages of 20 and 25 years, and of 100 cases occurring in adults of all ages no less than 38 occur during the first year of residence in India and 60 in the first two years. With regard to the second factor—that there was no field service going on in India in 1899—we have to remembe [illegible] Tirah field force, [illegible] all of which suffer [illegible] r. In the case of Quetta, where there had been a great decrease in the amount of enteric fever, this decrease might have been fairly attributed to the sanitary measures adopted in 1898 but for a significant footnote in the report that there had been a renewed outbreak in 1900. With regard to the effect which protective inoculation against enteric fever may have exerted it would be premature to form any decided opinion at present, but so far as we know and so far as India is concerned its effect seems to be favourable in safeguarding the constitution against attack. We have still, however, to await the results of the returns from the army in South Africa.

---

[1] THE LANCET, July 21st, 1900, p 199.

THE ROYAL SOCIETY CONVERSAZIONE.

THE annual conversazione of the Royal Society was held on May 8th, when an unusually large number of Fellows gathered together to witness the exhibits, to exchange ideas, and to welcome the new President, Sir William Huggins, K.C.B., D.C.L. The exhibits covered a very wide range of scientific subjects and for the most part were of a severely technical kind and beyond the grasp of the average man.

The beautiful experiments shown by Mr. J. E. Barnard and Dr. Allan Macfadyen of the Jenner Institute were, however, very generally appreciated. In a darkened corner of the library they exhibited luminous cultivations presenting an eerie blue light emitted by specific bacteria. The luminous properties of these bacteria, which are well illustrated in such familiar objects as dead fish, meat, and other substances, are dependent upon a supply of free oxygen and a suitable amount of a soluble chloride in the nutritive medium. The light ceases in the absence of oxygen, but on shaking a culture with air the whole mass glows brilliantly. Phosphorus has nothing to do with this, as has been popularly supposed. The light calls to mind that of luminous paint. By its aid a book may be read and the position of the hands of a clock made out. Equally attractive were the experiments of Mr. W. Duddell, who succeeded in drawing musical sounds from the electric arc light. This is done by superposing alternating currents on the direct current through the arc, the result being the setting up of vibrations producing a musical note. The pitch can be varied by altering the capacity or self-induction, and a tune can be played on the arc by this means. It was found during the evening that the tunes played on the experimental arc were simultaneously produced in the arc lights in other parts of the building and in the street. Representatives of the press were attracted most by the telegraphone, a combined telephone and phonograph receiving, recording, and transmitting. The instrument dispenses with the mechanical arrangement of a sharp point acting upon a wax surface, the whole performance being brought about by induced currents. A message may be received along a single cable and distributed at the same time through any number of wires. Moreover, it is calculated to curtail the labour of heavy correspondence; messages of considerable dimensions can be recorded and packed off in very small compass on a steel ribbon. A speech of an hour's duration may be thus contained on a steel ribbon occupying not more than a litre of space.

Specimens of the so-called "blood-rain," which fell in Sicily were shown by Professor Rücker and Professor Judd, C.B. In two experimental areas the dust collected was equal to a fall respectively of five and a half and nine and a quarter tons to the square mile. It is said that this dust derived from Northern Africa was noticed as far north as Hamburg. Close by these specimens were some huge specimens of chromium, manganese and cobalt in the metallic state, obtained by reducing the oxides with finely divided aluminium. They were exhibited by Sir W. Roberts Austen, K.C.B. Mr. G. Abbott, M.R.C.S. Eng., illustrated "growth" in inorganic matter by his interesting specimens of the cellular or magnesian limestone simulating corals. The "molecular directive force" produces patterns suggestive of an organised structure. Dr. P. L. Sclater exhibited two bandoleers from the Congo State and made from the skin of a hitherto unheard-of mammal, probably allied to the zebra. The specimens were obtained by Sir Harry Johnston, Special Commissioner in Uganda. The Zoological Society showed living specimens of the heloderm from Arizona, the only venomous lizard known; and close by Dr. J. H. Gladstone exhibited some interesting specimens of ancient Egyptian gold from the tombs of the kings of the 1st dynasty, and next to these were some casts and photographs of Egyptian jewellery of the 1st dynasty, 4700 B.C., shown by Mr. Flinders Petrie, D.C.L. Amongst them were four bracelets which belonged to the Queen of King Zer.

One of the most interesting and important exhibits was the excellent collection of microscopical specimens illustrating West African Parasitology by the School of Tropical Medicine, University College, Liverpool. The objects included 12 new specimens of hitherto undescribed blood filariæ of birds. Further objects illustrated the life-history of the intestinal parasite (ankylostoma duodenale) of the chimpanzee. Close by this interesting demonstration Mr. J. Mackenzie Davidson exhibited some very pretty stereoscopic transparencies of electrical discharges, and also some stereoscopic skiagrams of bullet wounds, the photographs having been taken during the South African war. The exact position of the bullet is shown by mere inspection in the stereoscope. Mr. Eric S. Bruce's meteo-parachute, a new instrument for investigating the upper atmosphere, attracted a deal of attention by reason of its ingenuity and promised usefulness. It consists of a parachute containing the instruments—thermometers, for example—attached to a balloon. By means of a clockwork arrangement the parachute may be made to detach from the balloon at any given moment, bringing the record of observation gently and gracefully to the feet of the investigator. In fact, the meteo-parachute ensures the safe return of the recording instruments to the ground at any moment that the experimenter determines before the ascent of the balloon.

We understand that the usual second conversazione of the Royal Society, an event generally known as Ladies' Night, will not be held this year owing to the death of Queen Victoria.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6517 births and 3799 deaths were registered during the week ending May 4th. The annual rate of mortality in these towns, which had been 19·7, 18·9, and 18·4 in the three preceding weeks, further declined last week to 17·3 per 1000 of the population, provisionally estimated, on the unrevised results of the recent census, to be 11,469,114 persons in the middle of the year. In London the death-rate was 16·7 per 1000, while it averaged 17·7 in the 32 large provincial towns. The lowest death-rates in these towns were 9·7 in Croydon, 11·5 in Leicester, 12·7 in Wolverhampton, and 13·2 in West Ham; the highest rates were 21·3 in Sunderland, 21·6 in Bolton, 24·1 in Gateshead, and 26·5 in Swansea. The 3799 deaths in these towns included 394 which were referred to the principal zymotic diseases, against 346 and 363 in the two preceding weeks; of these, 133 resulted from whooping-cough, 107 from measles, 55 from diphtheria, 45 from diarrhœal diseases, 34 from scarlet fever, and 20 from "fever" (principally enteric). No death from any of these diseases was registered last week in Croydon, Plymouth, Huddersfield, or Halifax; in the other towns they caused the lowest death-rates in Wolverhampton, Norwich, and Oldham, and the highest rates in Portsmouth, Bolton, Hull, and Gateshead. The greatest proportional mortality from measles occurred in Portsmouth, Liverpool, Bolton, Hull, and Gateshead; from scarlet fever in Preston; from whooping-cough in Swansea, Birmingham, Derby, Manchester, Bradford, and Hull; and from diarrhœal diseases in Swansea. The mortality from "fever" showed no marked excess in any of the large towns. The 55 deaths from diphtheria included 20 in London, six in Sheffield, five in Salford, four in Manchester, and four in Leeds. No fatal case of small-pox was registered in any of the 33 towns; and no small-pox patients were under treatment during last week in any of the Metropolitan Asylums hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1705, against 1601, 1526, and 1522 on the three preceding Saturdays; 371 new cases were admitted during the week, against 205, 150, and 198 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 374 and 286 in the two preceding weeks, further declined last week to 251, and were 78 below the corrected average. The causes of 45, or 1·2 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Leeds, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Liverpool, Halifax, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·1 to 22 9 per 1000 in the four preceding weeks, further declined to 21.2 during the week ending May 4th, but showed an excess of 3 9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 18·9 in Leith and 19·4 in Aberdeen to 24·0 in Dundee and 25 0 in Greenock. The 666 deaths in these towns included 39 which were referred to whooping-cough, 17 to measles, 12 to diarrhœa, eight to scarlet fever, three to small-pox, two to diphtheria, and two to "fever." In all, 83 deaths resulted from these principal zymotic diseases last week, against 95, 117, and 120 in the three preceding weeks. These 83 deaths were equal to an annual rate of 2·6 per 1000, which was 0·8 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 51, 56, and 62 in the three preceding weeks, declined again last week to 39, of which 16 occurred in Glasgow, 15 in Edinburgh, and eight in Dundee. The deaths from measles, which had increased from 16 to 25 in the four preceding weeks, declined again to 17 last week, and included six in Glasgow, four in Edinburgh, four in Leith, and two in Paisley. The fatal cases of diarrhœa, which had been 23 and 13 in the two preceding weeks, further declined last week to 12, of which four were registered in Glasgow, three in Edinburgh, two in Aberdeen, and two in Leith. The eight deaths from scarlet fever corresponded with the number in the preceding week, and included six in Glasgow. The fatal cases of small-pox, which had been six, 10, and three in the three preceding weeks, were again three last week, and were all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 130 and 169 in the two preceding weeks, declined again last week to 125, but slightly exceeded the number in the corresponding period of last year. The causes of 40, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 35 6, 35·4, and 29 4 per 1000 in the three preceding weeks, further declined to 26·5 during the week ending May 4th. During the past four weeks the death-rate in the city has averaged 31·7 per 1000, the rate during the same period being 17·8 in London and 23·8 in Edinburgh. The 176 deaths of persons belonging to Dublin registered during the week under notice were 19 below the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 18 and 10 in the two preceding weeks; of these, nine resulted from whooping-cough, two from "fever," and two from diarrhœa. These 13 deaths were equal to an annual rate of 2·0 per 1000, the zymotic death-rate during the same period being 1·7 in London and 4 2 in Edinburgh. The fatal cases of whooping-cough, which had been nine and eight in the two preceding weeks, rose again last week to nine. The deaths from "fever," which had been two, three, and one in the three preceding weeks, rose again to two last week. The 176 deaths in Dublin during the week under notice included 22 of children under one year of age and 43 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Two inquest cases and two deaths from violence were registered; and 62, or more than a third, of the deaths occurred in public institutions. The causes of five, or nearly 3 per cent, of the deaths in the city last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Staff Surgeons: A. E. Weightman to the *Pegasus*, and G. T. Collingwood to the *Diadem*. Surgeon B. Scribner to the *Duke of Wellington* for disposal.

Royal Army Medical Corps.

Brigade-Surgeon-Lieutenant-Colonel James Duncan, 3rd Volunteer Battalion the Manchester Regiment, is granted the temporary rank of Lieutenant-Colonel whilst serving in South Africa. Major Samuel Cowell Philson is seconded for service on the staff. Lieutenant Graham is ordered from Aldershot to Lichfield for duty. Lieutenant Wood has arrived at Aldershot and has been posted to the Depôt. Lieutenant Davies is appointed to the medical charge of the 1st Infantry Brigade at Aldershot. Lieutenants A. D. Jameson and H. R. Bateman hold themselves in readiness to embark for service in Egypt. Lieutenant H. E. M. Douglas, V.C., D.S.O., on arrival from England, is posted to the Decsa District.

Army Medical Reserve of Officers.

Surgeon-Major J. J. A V. C. Raye, who resigned his commission on Sept. 15th, 1897, is granted, in recognition of his service in the field, permission to retain his rank and wear the prescribed uniform.

Volunteer Corps.

Artillery: 1st Dorsetshire (Southern Division Royal Garrison Artillery): Surgeon-Lieutenant D. J. Lawson to be Surgeon-Captain. 1st Monmouthshire: Surgeon-Captain D. T. Richards resigns his commission. *Rifle:* 3rd Volunteer Battalion the Gloucestershire Regiment: Thomas Moravian Carter to be Surgeon-Lieutenant. 2nd Volunteer Battalion the East Lancaster Regiment: Charles William Crawshaw to be Surgeon-Lieutenant. 3rd Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant H. M Brownfield to be Surgeon-Captain. 1st Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Lieutenant E. A. C Baylor resigns his commission. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant-Colonel G. Griffiths retires, with permission to retain his rank and to wear the uniform of the battalion on retirement. 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal Highlanders): Supernumerary Surgeon-Captain C E. Douglas to be Surgeon-Captain on the Establishment. 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Lieutenant R. A. Fegan to be Surgeon-Captain.

Volunteer Medical Staff Corps.

The Glasgow Companies: Surgeon-Major G. T. Beatson to be Surgeon-Lieutenant-Colonel. The Manchester Companies: William Riddell Matthews to be Surgeon-Lieutenant; Charles Edward Preston to be Surgeon-Lieutenant.

Volunteer Officers' Decoration.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force: *North-Eastern District: Rifle:* 2nd Volunteer Battalion the Lincolnshire Regiment: Surgeon-Lieutenant-Colonel George Frederick England. *North-Western District: Rifle:* 2nd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant-Colonel George Westby; 2nd Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Lieutenant-Colonel Edward Morton Garstang. *Scottish District: Artillery:* 1st Edinburgh (City) Volunteer Artillery: Surgeon-Major George Ritchie Gilruth. *Rifle:* 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Major Walter Smith Cheyne. *Southern District: Rifle:* 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Surgeon-Captain Charles Sage Ticehurst.

Mentioned in Despatches.

In a despatch from Lord Kitchener, G.C.B., &c., Commander-in-Chief, South Africa, to the Secretary of State for War, dated Army Headquarters, Pretoria, March 8th, 1901, the following officers are mentioned for valuable services rendered:—Major F. Daly, R.A.M.C.; Lieutenant C. Challis, R.A.M.C.; Civil Surgeon G. Mowatt, attached R.A.M.C.; Civil Surgeon V. Robinson, attached R A.M.C.; Civil Surgeon Ellis, attached R A.M.C.; Civil Surgeon Caldwell, attached R.A.M.C.; Civil Surgeon Simpson, attached R.A.M.C.; Captain T. A. Green, New South Wales Medical Corps; and Surgeon-Captain S. C. Godfray, New Zealand Mounted Rifles.

Although he is not a member of the medical profession we are pleased to note that Sir Savile B. Crossley, whose benevolence and connexion with the Prince of Wales's Hospital Fund and the Metropolitan Hospital Sunday Fund are well known, is mentioned in Lord Kitchener's despatches.

AFFAIRS IN SOUTH AFRICA.

There is little or nothing of a decisive character to chronicle in the way of war news from South Africa. The losses in stores, ammunition, cattle, and vehicles on the part of the Boers have become chronic, but the enemy continue their elusive tactics and the battle which we were told was imminent with Delarey's force in the western Transvaal never came off. It seems only necessary for an announcement of this sort to appear in the papers for it not to happen. Nor should this be any matter for surprise, for the only practicable policy for the Boers to pursue at the present time is to abandon a position when pressed and to split up into small bodies and to scatter their forces. They are only likely to attack when in greatly superior numbers and to confine their attention mainly to raids on railways. Apart from the difficulty entailed by the vast extent of territory which has to be defended by the British, the Boers still seem to have little or no difficulty in obtaining information as to our intended movements. If we may judge from what we hear from correspondents in South Africa the belief is that this will continue so long as so many means of communication with the Boers remain open. The experiment of establishing a field force canteen, initiated under the management of Colonel Morgan, Director of Supplies, for supplying the troops with extra necessaries at cheap rates, has proved very successful. The system is being widely extended and is likely to prove a great boon to the troops. The plague continues to make progress in South Africa. The total number of cases since the outbreak of the disease is 572, of which 250 have terminated fatally. The debarkation of troops will probably have to be transferred from Cape Town to other uninfected ports, and as a preventive measure, Green Point, the principal camp near Cape Town, will probably have to be removed to another site. The large stock of commissariat stores and grain accumulated there attracts, of course, large numbers of rats which it is necessary to exterminate. Enteric fever is still prevalent, although to nothing like the extent that it was, and cases of dysentery are of frequent occurrence, but, taken as a whole, the British troops are healthy, though heartily sick of following a foe who never stands but always runs on their approach and takes every opportunity of "sniping" from safe and concealed cover. The following is the last published official return of our losses:—

—	Officers.	Non commissioned officers and men
Total reduction of the military forces through war in South Africa:—		
Deaths in South Africa	714	14,264
Missing and prisoners	7	774
Invalids sent home who have died	4	314
Invalids sent home who have left the service as unfit	—	2,493
	725	17,845
Total	18,570	

SOUTH AFRICAN WAR NOTES.

Civil Surgeon D. Massey-Burnside is reported dangerously ill with enteric fever (Harrismith, May 5th).

The following officers are returning home:—Major R. E. Kelly, R.A.M.C., Captain P. Evans, R.A.M.C., and Civil Surgeons Fry, L. H. Stephens, R. M. Geach, Charnley Smith, J. S. Warrack, and C. A. Peters.

Lieutenant W. H. Odlum, R.A.M.C., is reported slightly wounded doing duty with General Rundle's force April 24th.

THE LATE HONOURS GAZETTE.

The *Broad Arrow* of May 4th, 1901, says: "The officers of the R.A.M.C. are generally of opinion that a slight has been cast on the head of their department owing to the name of the Director-General having been omitted from the recent Honours' List. The Quartermaster-General and the Director-General of the Ordnance have been granted rewards for their services in connexion with the war, but the head of the Medical Department of the Army, whose duties have been most onerous, has received no recognition of his labours. The present Director-General has been a C.B. for several years, so that at least a K.C.B. might have been conferred upon him, considering that this honour has been held by every former Director-General of the Army Medical Department. It is therefore not surprising to find that the officers of the R.A.M.C. regard the omission in question as a pointed want of appreciation of good work. The Director-General was in no way responsible for any shortcomings of the medical arrangements in South Africa, and it is pretty certain that if the late Secretary of State for War had acted at first on the advice tendered by the Director-General on departmental matters much of the confusion and inability to cope with the enormous difficulties which have since beset his department in the present campaign would have been avoided." Another reference to this matter will be found on page 1350.

MEMORIAL TO THE LATE MAJOR HILLIARD.

A granite memorial column, designed by Mr. A. Y. Nutt, architect, has been dispatched by Messrs. Fountain and Co., Eton, to Durban, to be fixed at Newcastle, South Africa, in memory of Major George Hilliard, R.A.M.C. The inscription on a brass plate runs as follows: "Sacred to the memory of Major George Hilliard, R.A.M.C., who died at Newcastle, September 7th, 1900, from wounds received in a reconnaisance near Ingogo on the 5th.

Soldier of Christ, well done;
Praise be thy new employ,
And while eternal ages run
Rest in thy Saviour's joy.

Erected in grateful remembrance of the devoted care he rendered her husband by Beatrice, Princess Henry of Battenberg."

The *London Gazette* of May 7th contains the following:—"*Errata.*—The name of the officer brought to notice for his services in South Africa is Major Roger Kirkpatrick, Royal Army Medical Corps, No. 4 Stationary Hospital, and not as stated in the *Gazette* of Feb. 8th, 1901 (page 948), and April 16th, 1901 (page 2618).—The description of the undermentioned officer brought to notice for his services in South Africa in the *Gazette* of April 16th, 1901, and appointed Companion of the Distinguished Service Order in the *Gazette* of April 19th, 1901, is as now stated:—Surgeon-Major W. T. F. Davies, Imperial Light Horse (page 2610, April 16th, 1901, and page 2702, April 19th, 1901)."

A correspondent of the *Times* calls attention to the fact that while others have been sent home R.A.M.C. Volunteers, after more than a year's service, are being detained in South Africa, in many cases (for instance, where they are medical students) with much detriment to their future. No doubt the official reply would be: "They volunteered till the war was over"; but, surely, the correspondent continues, the authorities cannot wish to make volunteering unpopular among a class of men who offered valuable services freely.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the President, Vice-President, and Council held on May 7th the following examiners were elected:—Anatomy, A. Birmingham and A. Fraser; Surgery, H. Gray Croly and R. F. Tobin; Biology, J. J. Burgess; Ophthalmology, A. H. Benson and W. Story; Pathology and Bacteriology, A. H. White; Pathology, G. B. White; Midwifery and Gynæcology, F. W. Kidd; Sanitary Law and Vital Statistics, J. C. H. B. Goulding; Engineering and Architecture, J. C. Wilmot; Dental Surgery and Pathology, D. Corbett and W. Story; Mechanical Dentistry, G. M. P. Murray and W. Booth Pearsall; Chemistry and Physics, E. Lapper and J. R. Montgomery; Languages, L. J. Woodroffe; and Mathematics, Physics, Dictation, and English Essay, J. W. Tristram.

Correspondence.

"Audi alteram partem."

"RE-ORGANISATION OF THE ARMY MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 27th, p 1224, you have given us your proposals on the above subject in sequence to your summaries on the South Africa Commission, and as one having a profound belief in the potency of the medical and sanitary sciences to secure the physical efficiency of the military force during peace and war, and retaining a strong interest in the Army Medical Service despite retirement for some five years after 35 years spent in it, I would like to offer a few remarks on this important topic.

Now the South Africa Commission in their recommendations, very rightly in my opinion, express no desire to alter in any way the existing framework of the Royal Army Medical Corps; they favour no change in the system which now places under it the charge of the health of the army and the care of the sick and wounded; they recognise the necessity of its officers being at the head of each administrative and executive sphere; and so far as *materiel* is concerned they limit their suggestions to an increase of the amount of it and an improvement in the ambulance and the hospital marquee. The modifications they do suggest concern mainly the *personnel*—the development of a professional staff well fitted by ability and numbers when supplemented by an efficient nursing staff of female nurses and trained orderlies and a sufficiency of material means to reasonably safeguard the well-being of the army in peace and insure as full care of the sick and wounded in war as military exigencies may permit; and they propose to effect this end by an expansion of the present *personnel* and the formation of an efficient reserve, by attracting into the corps medical men of good professional attainments, by retaining them at a high level through furnished opportunities to inform themselves on all scientific advances and by selecting men for the higher posts for professional merit rather than by seniority, and by the employment of officers of the Royal Army Medical Corps in army sanitary work in peace and war. Such, tersely put, are the lines drawn out in the proposed re-organisation, and I infer from your remarks preceding your respective recommendations under definite headings that you are in accord with the Commission on these principles and that the 19 proposals you bring forward are to be regarded not as supplanting but as supplementary to them, embracing topics not touched upon by the Commission as a rule; and I think that no one with practical knowledge of army work and its requirements will fail to see the importance of the suggestions you make. That the departmental or other official committee suggested by the Commission for the drawing up of the necessary details to give a working expression to their opinions will have plenty of material to operate upon is apparent, and as it seems to me the duty of all to help on this important future work with the view of making the scheme as hopeful as possible I would like to make a few comments on some of your suggestions.

In respect to "the status of the Director-General" I would suggest, in addition to your proposals under this heading, the desirability of emancipating him and the department from their present complete subordination to the Horse Guards section of the War Office, and the necessity of this official being always drawn from the corps and selected solely on administrative and professional grounds; and in him and an improved "headquarters bureau" should be vested the power and responsibility of selection throughout the corps and of all advancements of officers to higher posts, be the grounds and occasion what they may.

In respect to your proposals touching the Army Medical School and its transfer to London it is desirable to bear in mind that at present it and the Netley Hospital are closely associated and that the former is vastly enhanced in value by the latter. When the school was formed the subjects taught in it were not elsewhere taught—a feature no longer pertaining to it—and its present value *per se* is probably to be found in its moulding the knowledge obtained in the civil schools to the requirements of the military sphere and teaching the professional care of the wounded during war. Through its association with the hospital the student can obtain a practical knowledge of army diseases, their morbid anatomy, and war injuries not elsewhere obtainable, as well as a practical initiation into the routine of military hospital duties To remove the school alone to London would deprive it of this most valuable adjunct. If both school and hospital could be transferred to a site sufficiently near London to allow of full action of the military and civil professional elements, the one or the other, gain would unquestionably result. Hence the view I take, after several years of work in the school, is that to the medical candidate loss, not gain, would result by its transfer alone to London; while as regards the medical officer returning from foreign service he is far more likely to find his wants better supplied in civil hospitals and schools than in a course of instruction as at present given at the Netley School or in the practice of its hospital. That the school might be overhauled with advantage may be advanced without aspersion on its present staff, and that gain would result by re-transfer to Netley, or wherever the school and hospital might be located, of the Aldershot establishment for orderly and military instruction—bereft of it to the well-recognised disadvantage when effected many years ago—will probably be agreed to by those having had former experience of the good results of the combination.

With regard to the proposed abolition of the entrance examination, if I mistake not its original purpose was two-fold—to allow of the placement of men in accord with the results of competition and to obtain by a higher qualifying test than that in force in civil life a class of men, for what was then considered the highly important sphere of medical military work, above the ordinary professional average. For many, many years past competition has disappeared—a regretted relic of the early sixties and Mr. Sidney Herbert's noble work—and the difficulty has been to get men in any way, and the present examination test—that of the London Conjoint at least, though whether all other boards conform to this standard may be questioned—is a sufficient guarantee of ability for military medical duty, hence there are strong *prima-facie* grounds for its abolition, especially when the present system of nomination to appointments is borne in mind. Yet some means of grading the candidates is necessary, and if the subjects taught in the Netley School are to be taken for the purpose, in what way is the quality of those who have held hospital posts and possess degrees and high diplomas to obtain proper recognition? Under such a plan those better men who have probably given an extra year or two in obtaining this extra quality may find themselves placed not before but on an equality with, or even below, men younger than themselves—no small disadvantage with the present time limits to promotion to the higher posts and retirement on good and full pension. And with respect to the proposed substitution of an examination within the first 10 years of service with its two grades of pass and honours if the end of the honour attainment is to rest with the "asterisk or some distinguishing letters" after the name in the Army List (more than probable unless the whole system of promotion be changed) the advantage to the individual so distinguishing himself is not discernible. If I may express an opinion it is to the effect that some test (for instance, an examination not necessarily identical with that already passed for qualification but embracing subjects specially selected for the purpose) at entrance is necessary for *all* applicants for army employ to give fair play to those eminently desirable individuals possessing degrees or having had practical experience in hospital posts or otherwise, and that the examination after entrance—say at eight or ten years—should be in character both qualifying and competitive, the officers so placed under the latter phase to advance to the next grade in advance of the merely qualifying men, thus bringing in the stimulus of personal professional improvement at an early period in the career of the individual as well as, as suggested, at the later period when he is reaching the administrative grade.

With these comments on those of your valuable proposals which seem open to criticism, will you allow me, Sirs, to express my regret at not finding greater stress laid by you on the necessity of making professional ability, merit, and work one chief ground for promotion in the corps of the future in order to engender that healthy stimulus to scientific advance which alone can insure a thoroughly efficient body of officers for the important medico-chirurgical hygienic army work?

True, you express the opinion that there should "be far more rewards held out for professional merit," yet as you previously remark that "there are no means, or very few, of rewarding medical officers for professional distinction or scientific work in the service," a hopeless *impasse* is brought about unless the way be opened up by advance from one grade to another. You mention that "promotion by selection has been apparently attended with so many difficulties that it has never been strictly adhered to," but is it not more in accord with fact to say that in spite of the Royal warrant after the Crimean inquiry it has never yet been put in practice, if ever suggested, by the powers that be, Commander-in-Chief or Director-General? There has been no difficulty in advancing men on various grounds other than professional with the dangerous result (probably explanatory of some of the asserted shortcomings) of showing the corps that so far as advancement was concerned the very *raison d'être* of its existence was the one point which could be safely ignored. It is sincerely to be hoped that this great motive force for progress in all avocations in life will receive full recognition in the proposed re-organisation, for without it where is the attraction for the "talented alumni of our schools and colleges," what avails the most perfect material fabric? It was recognised as necessary in 1858, why is it less necessary in 1901? The hopes then held out brought full competition into play and an excellent class of men into the service in 1860-61 and thereabouts; these hopes were never realised, and we know the degraded condition into which the department passed from this and other reasons; and are these sad experiences to be ignored in the future?

Well, Sirs, we all look for a good issue to this South African inquiry, but it may be safely said that unless the corps be freed from the trammels of so many of the War Office sections now potent to mar it, and allowed to advance and develop itself on its own self-knowledge and on business principles, no scheme, however otherwise complete, will avail to give the nation what is required in order to prevent a repetition of the past disasters.

I am, Sirs, yours faithfully,
FRANCIS H. WELCH, F.R.C.S. Eng.,
Surgeon Colonel (retired) Medical Staff.
Brandram road, Lee, S.E., May 4th, 1901.

To the Editors of THE LANCET.

SIRS,—You were good enough to publish in THE LANCET of May 4th, p. 1300, a letter of mine suggesting the formation of an army medical school for the purpose of training students for the Army Medical Corps. I purpose this week to trespass again on your space in order to give my scheme in more detail.

1. Entrance to the school should be by competitive examination in arts. The examination should be held at the same time as the examination for Sandhurst and the papers should be the same. Age-limits should be 16 to 18 years.

2. The course at the school should be of five years' duration, and the examinations for which the student should be prepared the M.R.C.S., L.R.C.P. Lond. The order of passing out should be determined by success at the college examinations.

3. I would make the school somewhat on the lines of Cooper's Hill—i.e., I would offer a limited number, according to vacancies, of appointments in the navy, army, Indian, and colonial services to candidates who had done best at their first two examinations.

4. Students at the college should be under military discipline the whole time. For the army and navy candidate discipline is essential, and the others will be no worse for it.

5. During part of the vacation the army and Indian candidate should be sent to Aldershot to learn riding and bearer-company work.

6. Where should this school be? It must, of course, be at a great medical centre and I think it resolves itself practically into the choice of four centres—London, Edinburgh, Cambridge, or Dublin. Dublin is not desirable, being the wrong side of St. George's Channel. Cambridge, though probably most pleasant, cannot give the clinical experience necessary. It resolves itself, I think, into a choice between Edinburgh and London. Edinburgh offers many advantages, such as the great facilities for teaching, the ease with which a wing of the hospital could be reserved for candidates from the army school, the healthy situation, and its great opportunities for sport of all kinds. London, on the other hand, has one great advantage—viz., its proximity to Aldershot. If London be chosen I would suggest that the school be attached to the West London or some other hospital where students are not at present working.

7. Numbers. About 30 commissions are required a year for the navy, 30 for the Royal Army Medical Corps, 30 for the Indian Medical Service, and say 10 for colonial appointments. Total for the year, 100. Grand total for five years 500. Allow an extra 100 or so, and you have a school of 600 men, which is quite sufficient for working purposes.

8. Expense. I would make ordinary candidates pay £120 a year—sons of officers to be given a reduction—as at Sandhurst or Woolwich. All necessary examination fees to be paid by Government.

9. Failure at examinations to be satisfactorily explained, with the alternative of dismissal.

10. The head of the school to be a surgeon-general, assisted for purposes of discipline by officers of the Royal Army Medical Corps. The teaching staff to be well-paid civilians.

11. On "qualifying" commissions should be granted and the most deserving officers should be given "house appointments."

12. Officers should then be given a short course of military hygiene, medicine, and surgery as at present, but this course should be transferred from Netley to the Army Medical School.

These suggestions are, of course, open to many objections, but I feel certain that if the State wants army medical officers of the right stamp they must take the trouble to train them up carefully from the first, as they train the "sapper" and "gunner."—I am, Sirs, yours faithfully,

May 6th, 1901. R.A.M.C.

"THE ACTION OF ARSENIC AS OBSERVED DURING THE RECENT EPIDEMIC OF ARSENIC POISONING."

To the Editors of THE LANCET.

SIRS,—I am moved to write to you by an allusion to me in Sir T. Lauder Brunton's article in THE LANCET of May 4th, p. 1259. Not that I have anything to complain of (unless of one rather too unqualified statement attributed to me), but only that if the facts are (as they appear to Sir Lauder Brunton to be) "remarkable" or interesting in any degree in connexion with a subject which has been investigated by a Royal Commission, it is well that they should be on record in your columns exactly as I stated them to Sir Lauder Brunton and others near the commencement of the "arsenic scare." At the time in question (about 16 years ago, I think) the late Dr. James Ross had been much occupied with what he and others then called "alcoholic paralysis," and in a general way I had been struck with the paucity of instances of this disease (assuming it to be a separate disease and rightly so named) in Glasgow. Being well aware, however, how easy it is to overlook a disease which is unfamiliar, I asked Dr. Ross to be so kind as to demonstrate to me several cases, of which I think he said that he had about half a dozen in his wards at the time. I was much impressed with the novelty, to me, of the whole *symptomen complex* and told Dr. Ross so, adding that if this form of paralysis was really "alcoholic" I should have expected it to be quite as common and as well defined in Glasgow as in Manchester. The latent conviction then in my mind was that there was some other toxic agent rather than the alcohol, though associated therewith, that underlay the etiology of the affection. Further observation for several years only confirmed me in this view, though I never committed myself to such an unqualified statement as that the disease "did not exist in Glasgow." Indeed, both in hospital and in private practice I saw a sufficient number of cases to assure me that my diagnosis previously had not been at fault, but at the same time to confirm generally the view that alcohol could not be the sole, or even the most essential, cause of the disease. The rapidly extending literature of peripheral neuritis and the comprehensive and valuable posthumous work of Dr. Ross (in conjunction with Dr. Judson Bury) were most carefully studied by me and became the basis of my clinical teaching on this subject, but still without any clear light occurring as to what the detrimental substance was until the "arsenic scare" arose, when I felt it to be my duty to tell in various quarters my previous experience as a contribution to the history of the subject.

I am, Sirs, yours faithfully,
W. T. GAIRDNER.
Edinburgh, May 6th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE"

To the Editors of THE LANCET

SIRS,—Dr T S Clouston[1] is perfectly right in denouncing my comparison of the craving for alcohol to an instinct (an inborn trait) I made it in my first publication, but soon becoming conscious of my error, substituted for it a truer definition in subsequent publications with some of which Dr Clouston is acquainted[2] No critic had then commented on it, and Dr Clouston is the first to do so This by the way Meanwhile, I do not know that any good can come of the present controversy unless we keep to the main points at issue We deal with a very grave matter, and are not, I hope, mere dialecticians

I stated originally that, on biological grounds, temperance reform was impossible, and could lead ultimately only to increased drunkenness I propounded an alternative remedy My opponents declared it impracticable "Very well," I replied, ' what, then, is your remedy? Temperance reform! But temperance reform has been tried for thousands of years, and has almost invariably failed It has been tried lately on a very large scale in the modern civilised world will you mention a single instance in which it has succeeded under conditions half as onerous as the least onerous that exist anywhere in England? I personally am prepared to prove that all such attempts have resulted in increased drunkenness as well as in many other attendant evils" In effect my opponents reply "We cannot tell you of such a case But that is not the point We are able to tell you of something entirely different—of instances in which temperance reform has done some good under conditions remotely unlike those which prevail in England, under conditions which are rapidly disappearing from the civilised world, and under which not one civilised man in a thousand now lives Moreover, you are a pernicious person, your opinions are very dangerous We implore you not to put a spoke in the wheels of temperance reform Let the reformer continue his beneficent work We are astonished at your lack of humour and at your persistence"

I do not exaggerate in the least It all seems to me very Gilbertian, but I daresay that that is owing to my Scottish lack of humour I confess I am somewhat bewildered If I am wrong, it is so very easy to prove me wrong An immense mass of data is to the hand of every student If I am right, the temperance reformer is—well, not precisely a beneficent person He does not reform and prohibition does not prohibit

"How drunkenness has greatly increased in Norway of late years on a greatly diminished quantity of alcohol" passes Dr Clouston's comprehension I have already explained that it is through the extinction of the moderate drinker. The moderate drinker is easily deterred by prohibition, the drunkard will go through fire and water to obtain the satisfaction of his desires I am sorry to contradict an opponent so courteous, but as a fact he is in error Messrs Rowntree and Sherwell state in the plainest terms that both drunkenness and the *per capita* consumption of alcohol have increased during recent years in Norway[3]

Dr Clouston complains that police returns are very fallacious He is quite right Here is an example It shows how police returns are affected by prohibition—by "temperance reform" In Portland the arrests for drunkenness have increased from 16 per 1000 for the years 1852–1856 to 42 per 1000 for the years 1898–1899 The late General Neal Dow, the great protagonist of reform speaking in Portland in 1893, said "When I was mayor (in 1851) every man who indicated that he was drunk was arrested but now they do not do that unless the man is noisy and disturbing the peace"

The following is an example of how prohibition works I take it from the *Westminster Gazette* of May 19th, 1898 I am ready to quote any number of similar instances "The Clutha prohibition is not the only one we have had in New Zealand A local option law existed in this colony many years ago Under its provisions it was open to the people in any district to vote 'no licence' In the North Seventy Mile Bush, in the Hawkes Bay province in a township called Ormondville, a man who had drunk himself mad went home one day and murdered his wife and four or five children Naturally a thrill of horror passed through the district, and when the next local option poll was taken the people voted solidly and solemnly for 'no licence' The public houses in Makotutu, Ormondville, and Norsewood were closed for three years Did drinking and drunkenness cease? No The drinking customs of the people underwent a change for the worse; sly grog selling became rampant and more liquor was ordered for consumption in that district than ever before or since In private houses bottles were kept from which anyone might help himself, so long as he deposited the requisite sixpence per nip on the mantelshelf In more than one instance this led to the women of the household cultivating a taste for liquor Secret rooms were fitted up as bars where every kind of liquor was dispensed, and in some of these shocking scenes were witnessed Meantime the business of the township suffered, as travellers were compelled to pass on to neighbouring towns to obtain accommodation Visitors who had been in the habit of spending a few weeks in the bush for health's sake were prevented, for the same reason, from sojourning in the district Drunkenness and debauchery increased, and so soon as the prescribed period of prohibition had passed the people voted to reopen the hotels'

It is scarcely necessary to reply at length to Dr Gordon Sharp[4] It seems that he has "done Dr Archdall Reid the justice of reading most of, if not all, his letters and papers on this alcohol and heredity question," but he says, "I am afraid I have not yet grasped his meaning" All the points raised by him have already been dealt with in the publications he alludes to, and by this person and that my meaning appears to have been grasped clearly enough I greatly regret that I am unable to make myself comprehensible to Dr Sharp The fault is mine But Dr. Sharp betrays an intimate knowledge of a subject of which I am an eager student He says "All peoples have known alcohol in some form or other from their earliest antiquity" I have collected information on this point of most of the races of the world, but I am yet ignorant of the alcoholic history of a good many races—for example, the Terra del Fuegians the Patagonians, the Australasian natives and the Esquimaux I am ignorant even of the sources whence they could have drawn their supplies of alcohol Will Dr Sharp kindly inform me? I want precise details—references to this or that authority

I am, Sirs, yours faithfully,

Southsea, April 28th 1901 G ARCHDALL REID

To the Editors of THE LANCET.

SIRS,—Before this question passes away from the region of discussion, and in order that Dr Archdall Reid's views be not left in possession of the field, I beg to draw attention to an important fact which bears on the practical side of the matter Weismannism, with its allied doctrines, is far from being generally accepted by biologists, and Weismannism, as an articulated system of theories, stands or falls with the proof or disproof of the inheritance of acquired characters. Many educated persons feel as much interest in that doctrine and as much respect for it as Dr Johnson for a certain question in metaphysics which he dealt with by kicking a stone lying at his feet But the question of the *possibility*, not the frequent occurrence, of the transmission of acquired characters is vital to Dr Archdall Reid's position as to alcoholism Surely when first-rate biologists can write as Professor J Arthur Thomson[5] and Professor W K Brooks[6] on the need for further facts as to use inheritance it behoves those who deal with such profoundly important questions as that of national intemperance to walk warily and to speak humbly For this reason Dr Clouston's last and dignified rejoinder to his opponents is most valuable "Not proven" must be the verdict in this year of grace 1901 as to their much-disputed biological doctrine It may be remembered by your readers how very far Professor Berry Haycraft went in his Milroy Lectures for 1894 on Darwinism and Race Progress in the direction taken by Dr Archdall Reid and his friends He there boldly proclaimed tubercle, leprosy, zymotic diseases, and alcoholism as friends of the human race by virtue of their selective influence, though he refrained from that fatal love for strict orthodoxy which so generally characterises partisans, and maintained that syphilis, by virtue of its being a case of inherited "acquired characters," was an exception to the other friends of the human race, and, indeed, was an enemy. But he made a remark of extreme importance to such a painfully pressing matter as that before us, with which I will conclude. He says: "It is evident that in applying in practical matters the lessons that the biologists may teach us we must be certain that we are dealing with truths that will remain truths for this and for many generations."[1] I am, Sirs, yours faithfully,

THE DEATHS FROM (?) BOXING.

To the Editors of THE LANCET.

SIRS,—Surely the faculty ought to be able to help in throwing some sort of light on what appears to be a ghastly mystery in the matter of these last three deaths after boxing under apparently the safest of conditions—conditions non-existent in other clubs where great numbers of severe contests take place. The mystery has hitherto been treated as a *surgical* affair, but I cannot help thinking there is a *medical* aspect to it which may be worth while considering, especially as the mystery remains unsolved by the surgico-pathological theory. Admitting that intracranial hæmorrhage from a blow without fracture is "on the cards," I contend that, considering the millions of knocks, blows, and punches on the head which occur, it is most rare. In all these cases the boxing has been of such a high-class nature that no really violent blow was received on either side. In the first case, that of Turner, post-mortem examination revealed no lesion whatever—the only peculiarity that could be spoken of was that the heart was smaller than the average. Yet he had won an open competition, meeting the picked men in England, only a week or two before. He was to be married the week after the contest at the National Sporting Club and alone supported a widowed mother. What could he have died from but nerve collapse due to over-excitement and anxiety? Yet public opinion put it down very naturally to boxing, pure and simple—killed by it. In the cases of Riley and Smith the necropsy showed intercranial hæmorrhage with *no* external marks of violence, much less fracture. Now I put it in this way: if this "case" last week had been brought into the hospital, not as one from the National Sporting Club, but one found insensible, sitting on a doorstep, of course the strictest search would be made for signs of outward violence; finding none, post-mortem examination shows intercranial hæmorrhage. How would death be certified—from "violence" or from "natural causes"?

Apoplexy may be uncommon in the young and apparently healthy, but I contend that nerve tension would be much more likely to cause it than any outward violence, though the surgical evidence was that the hæmorrhage *could not* have arisen without external concussion. I have witnessed practically every round of the amateur boxing championships for the last 21 years, where infinitely more severe punishment is given and taken than in these three cases. St. James's Hall is packed from floor to ceiling, any amount of shouting and chaff being indulged in by the spectators, the din being terrific at times, yet never has anything serious happened to the boxers. Can it be that the very strict rule of "silence during the boxing" at the National Sporting Club has the effect of making the contest a much more intense mental strain to the competitor and conducing, therefore, towards nerve collapse and apoplexy? In all other clubs spectators are allowed to cheer or otherwise during the boxing, thereby letting off the steam of excitement for onlookers and competitors. The officials of the club must indeed be almost driven crazy at finding their well-intentioned efforts to provide for the safety of the boxers end in such lamentable failure, and to sportsmen who take an interest in boxing these deaths have been very pathetic and heart-breaking. One does not get "used" to these kind of sad endings to contests fought out, as they almost always are, with the best of good feeling and even generosity.

I am, Sirs, yours faithfully,
F. ORTON, M.D. Dub.

Crouch End, Hornsey, N., May 6th, 1901.

"THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to the letter of "W. E. T." in THE LANCET of May 4th, p. 1301. Will you allow me to advise him and his neighbours not to undertake medical attendance under the terms and conditions offered by the National Friendly Society, if by this he means the National Deposit Friendly Society? The Medical Guild has twice discussed the claims of this society and has on both occasions declined to work on its terms

I am, Sirs, yours faithfully,

Salford, May 7th, 1901. R. HANSON WOLSTENHOLME.

To the Editors of THE LANCET.

SIRS,—If the representatives of friendly societies and the General Medical Council will discuss their differences with the same spirit of fairness and anxiety for a definite settlement of the breach as is contained in Mr. Brabrook's letter, for which all medical men engaged in contract work will thank him, these constant disputes will soon be at an end. The wage-limit is a question upon which the friendly societies will never give in, and if the profession fight them on that question the result will be a further increase in the number of so-called "friendly societies medical institutions." The objects of these associations are laudable enough. It is often to be deplored that the friendly societies are under the impression that the medical profession attack the poor or working-classes who belong to these institutions; this is not so, the main cause for the dislike for these associations on the part of the profession is that they are largely composed of persons who can, and did formerly pay, a reasonable fee, and to fight against this we seem powerless. That the friendly societies do underpay their medical men can be proved over and over again. In Glasgow very recently a big lodge (A.O.F.) advertised for a medical man and offered 2*s.* 6*d.* per member per annum. He had to visit in a three-mile radius and find drugs, &c. A registered friendly society the members of which are nearly, if not all, employed at a Government dockyard offered 2*s.* 6*d.* per adult member and ½*d.* a week for each child and wife of the members. Again, at a recent conference of Friendly Societies several prominent members openly confessed that they underpaid their surgeons In my own district I have to pay an assistant £150, indoors My bill for drugs has considerably increased, the wages I pay have gone up—in short, my general expenses are much more than formerly. I have a colliery appointment and I put the question of a slight increase before the miners' committee and I met with refusal although I have been here since 1897, when the colliers got 25*s.*; in 1898, 27*s.* 6*d.*; in 1899, 29*s.* 4*d.*; in 1900, 33*s* 4*d.*; and in 1901, 34*s.* Wages have gone up generally, the working man's position has improved, and he can well afford to pay a fair sum for contract work. What is that sum?

I contend the majority of us would be satisfied with 4*s.* per annum for juveniles, 4*s.* per annum for adult male, and 5*s.* per annum for female, members. I have a club with 250 adult members who pay me 4*s.* per annum for each member, a sum I am satisfied to attend them for. They have established a juvenile club of 150 members, little boys and girls. They insist on my taking them at one halfpenny per member—6*s.* 3*d.* a week. This would mean about 4 per cent. on my list always. I pointed out that I would get nothing out of it, whereupon they threatened to withdraw the adult lodge or to join other societies in the establishment of an institution. It is in cases such as the one just cited where the friendly society members deal harshly with the doctor, in fact, any attempt on our part to combine with a view to remedy these grievances is looked upon by the trades union working man oddfellow as extremely aggressive. We only want what is fair and I hope Mr. Brabrook will use his influence with friendly societies towards that end.

I am, Sirs, yours faithfully,

May 6th, 1901. A COLLIERY SURGEON.

WATER IN BUTTER.—At the Bristol Police-court on April 30th a firm of butter manufacturers of Wellington, Somerset, were fined £21 for selling three samples of butter containing 28·3, 26 2, and 23·3 per cent. of water respectively.

---

[1] THE LANCET, Feb. 17th, 1894, p. 383.

GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

THE Congress of Internal Medicine met in Berlin on April 16th, Professor **SENATOR** being in the chair. In his inaugural address the chairman drew attention to the surprising improvements made in diagnosis during the century which had just closed. Not long ago a medical man could carry in his pocket all the instruments used for diagnosis, but at the present time even a Hercules would be overloaded with the bulky and complicated apparatus occasionally resorted to for diagnostic purposes. There was a time when diagnosis seemed to be the principal object of medical science and when a certain amount of "nihilismus" prevailed in therapeutics, but this was a thing of the past and diagnosis was now believed to be the essential preliminary of successful treatment. Professor Senator then mentioned some diseases the cure of which depended on an *early and exact diagnosis by modern methods, including the* use of the microscope, and closed his speech with the words, "Qui bene diagnoscit, bene curat." The first papers read before the congress were on subjects connected with the heart.

Cardiac Tonics.

Professor **GOTTLIEB** (Heidelberg) said that in disorders of the circulation the distribution of blood within the organism became altered and that by the use of cardiac tonics or vaso-motor stimulants the normal state might be restored. He described the distribution of blood in vaso-motor paresis where there was plethora of the abdominal circulation and anæmia of the peripheral circulation, the brain, and the skin. In this condition, which was due especially to poisoning or to acute infectious diseases, cardiac tonics were useless because the action of the heart was normal. Vaso-motor stimulants, however, acting on the splanchnic nerves might bring about an alteration in the distribution of the blood, compounds like strychnine, caffeine, and camphor being indicated, but not digitalis. Digitalis was useful when the action of the heart was feeble, for it increased the power of the heart, and Professor Gottlieb had found by experiment that under the influence of digitoxin the energy of a ventricle became three times stronger than before. An improvement of the pulse took place because the contractions of the heart-muscle became not only stronger but also less frequent, owing to the action of digitalis on the vagus nerve Digitalis also produced a contraction of the blood-vessels Camphor did not increase the force but only the irritability of the heart; its action was therefore only temporary; caffeine was useful when the blood-pressure in the aorta was high because it aided the heart to surmount such pathological resistances in the circulation. Alcohol also diminished the resistance because it dilated the blood-vessels.

Professor **SAHLI** (Berne) read a paper on the same subject. He said that a stagnation of the circulation might depend upon a variety of causes, and he distinguished four forms—viz.: (1) cardiac stagnation produced by an insufficient systole as well as by a mechanical hindering of the systole; (2) respiratory stagnation occurring in diseases of the respiration; (3) vaso motor stagnation produced by a paresis of the vessels of the great circulation; and (4) splanchnic stagnation with plethora of the abdominal and anæmia of the peripheric circulation. In all these cases digitalis was useful, but not in the so called essential stagnation—the condition which existed when in valvular endocarditis the defect of a valve had become so great that even in normal action of the heart stagnation was inevitable. The danger of digitalis was often exaggerated and if reasonably administered it might be given for a long time Professor Sahli finally explained the action of caffeine and camphor which were both vaso-motor stimulants and were valuable by reason of their action on the respiration and their diuretic effect As to the action of alcohol, he was of opinion that it did not produce a direct influence on the heart, but that it acted usefully by improving the circulation in shivering fits or when the reaction after a cold bath was insufficient. Professor Sahli finally explained how these compounds should be combined and administered.

Professor **SCHOTT** (Nauheim) was of opinion that practically there was no difference between cardiac tonics and vaso-motor stimulants. The principal requisite was to strengthen the heart.

Professor **GOLDSCHEIDER** (Berlin) said that the administration of digitalis ought never to be stopped at once, but smaller doses ought to be prescribed when the action of the drug was found to be too strong.

Professor **MENDELSOHN** (Berlin) reported some experiments on measuring the strength of the heart. The patient performed a certain amount of work in which the heart's action was increased and the interval after which it became normal again was noted.

Professor **KRAUS** (Graz) said that this experiment, to be valuable, must be repeated at certain intervals.

Professor **BAELZ** (Tokio) pointed out that the differences in individuals were very great; in Japanese messengers, for instance, who ran 100 kilometres (62 miles) a day without stopping, the pulse became of normal frequency almost at once after their work was done.

Artificial Hyperæmia as a Therapeutic Agent.

Dr. **BIER**, Professor of Surgery at Greifswald, on the invitation of the committee, read a paper on this subject. He said that he had used his method first in tuberculosis of the joints. It consisted in applying round the extremity above the affected joint a caoutchouc bandage which produced a constriction of the blood-vessels, stasis, and hyperæmia in the extremity. The bandage, if properly applied, might be tolerated for several hours at a time for many days. He had numerous favourable results in tuberculosis of the joints and accordingly had tried the method in rheumatic and gonorrhœal diseases of the joints. The venous stasis caused by the constriction was found to relieve the pains By the researches of Dr. Noetzel it had been proved that artificial hyperæmia had a bactericidal action and that the formation of fibroid tissue, and therefore cicatrisation, was promoted. Dr. Bier's artificial hyperæmia, moreover, arrested the absorption of the exudation, and this was especially important in rheumatic arthritis where this method was used together with massage.

Etiology of Acute Rheumatic Arthritis.

Dr. **SINGER** (Vienna) reported that he had made a microscopical examination of six cases of rheumatic arthritis and two cases of chorea. In every instance staphylococci and streptococci were present in the joints and in other organs. He was of opinion that rheumatic polyarthritis was an abortive form of pyæmia but that it was not caused by a specific bacillus, as suggested by some authorities.

Dr. **MEYER** (Berlin) held an opposite opinion. In 12 cases of rheumatic sore throat he had cultivated streptococci which when injected into animals produced exudations into the joints and serous membranes, endocarditis, and a condition very similar to acute rheumatic arthritis. The streptococci of rheumatic sore-throat had therefore a specific action.

Dr. **MENZER** (Berlin) said that he had succeeded in cultivating a streptococcus in endocarditis verrucosa which produced exudation into the joints and serous membranes *when injected into* the palate of rabbits. The *streptococci* found in rheumatic sore throat were not so virulent.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Consultative Institute.

IN THE LANCET of April 20th, p. 1171, it is noted that the authors of the Consultative Institute had made a change in their programme by advertising for a consulting physician and a consulting surgeon at a salary of £500 a year each. This was in place of the one consultant who recently resigned The holders of the office were to be debarred from private practice. Another change in the policy of the Institute has *just* been made in the form of a seductive inducement to outsiders It is now proposed to increase the number of the consultants to five and to give them each a sum of £200 a year with permission to engage in private practice also. An advertisement has appeared several times in the local papers for consultants and specialists for the posts of physician, surgeon, oculist, aurist, and gynæcologist. The remuneration offered is the fees of the patients less the working expenses, a minimum of £200 a year being guaranteed. A meeting of the Birmingham consultants and specialists was held at the Medical Institute on May 2nd, when the situation as indicated by the recent changes was considered. The general tone of the meeting was antagonistic to the Consultative Institute *in toto* on the present lines. The often-repeated objection to the ordinary consultants' fees was again made clear by the fact stated that the majority of consultants in the town are quite willing to see exceptional cases for a half-guinea fee. It was pointed out that the new Institute had no wage-limit or method of inquiry which would restrict its operations to the class for whom it was intended; also, that there was no representation of the profession upon its management, it being notorious that the present promoters had expressed themselves in terms most hostile to the interests of the profession. It is stated, on the other hand, that efforts are being made to draw the friendly societies of the town under the control of the Institute and so to influence the position of the general practitioners attached to them. However the medical attendant of one of these organisations may wish to make his choice of a consultant his recommendations will be of no avail if the society or club is affiliated to the new Consultative Institute. The present attitude of the profession is one of no surrender. It must be borne in mind that they have to deal with a determined opposition which shows little signs of compromise or conciliation.

A Crematorium.

The first annual meeting of the promoters of a crematorium for Birmingham was held on April 22nd. The report dealt mainly with the difficulties of finding a suitable site. Four months' search in many directions with various difficulties and objections resulted in obtaining a grant from General Calthorpe of an acre of land conveniently situated near the town at Perry Barr. Here it is proposed to erect the necessary buildings. The balance-sheet showed that 1239 shares of £5 each had been taken up and a donation of £500 had been received. There is every prospect of the project being carried through.

The Lying in Charity.

The fifty-eighth annual meeting of this charity was held on April 23rd. It was shown that much valuable work is done in an unostentatious way by the midwives and medical men connected with it Thus the number of cases attended during the year was 873, the services of the honorary medical officers being called for in 46 cases. The report of the medical committee emphasised the necessity of providing beds for difficult and operative cases, also of a provision for teaching and training nurses in this department. Some discussion took place, opinions being divided among the lay members as to the wisdom of making any changes from the present outdoor system of attendance. Serious reflection suggests the desirability of acting on the lines laid down by the medical committee which would be much to the public advantage. It is to be hoped that time will allow of these suggestions taking a practical and tangible form.

May 7th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary: Retirement of Mr. James Hardie.

AT the meeting of the Board of Management of the Manchester Royal Infirmary held on April 29th, Mr. Hardie, having arrived at the "fixed period"—i.e., the age-limit of 60 years—sent in his resignation as honorary surgeon. The chairman, Sir F. Forbes Adam, said that it was a source of regret to the board when under the rules cf the institution a good man ceased to be actively connected with them. He moved:—

> That, in accepting with much regret Mr. Hardie's resignation the board desired to place on record their high sense of the valuable services rendered by him during the past 25 years, and of the skill, ability, and kindly consideration he had at all times shown in the treatment of the patients, and that the board had much pleasure in appointing Mr. Hardie as honorary consulting surgeon of the institution from the date of his retirement.

This was seconded by Mr. E. S. Heywood, the late chairman, and was passed unanimously.

Hospital Saturday.

Saturday, May 4th, was Hospital Saturday, and an urgent appeal was issued for liberal contributions. For the last two or three years the claims made by the Indian famine and the war have reduced the collections. It is too soon to know the amount received this year, but last year the total of the Saturday and Sunday collections was £7233 14*s*. 4*d*. This is a small sum compared with the £25,000 collected at Birmingham. "The cases of illness treated in the voluntary and workhouse hospitals of Manchester and Salford in 1899 numbered 56 5 per cent. of the population and the deaths 2 3 per cent." If this means that considerably more than half of the people in Manchester and Salford have during the year received hospital treatment there is no wonder that the expenditure of the hospitals exceeds their income or that medical practitioners have begun to feel that charitable medical help is given with too lavish a hand. There is some danger in these philanthropic days of large sections of the people losing all idea of self-help and retaining but little of their self-respect.

£40,000 for Middle-class Baths.

The Baths Committee of the Manchester Corporation recommended at the council meeting held on May 1st that baths should be erected in High-street, Chorlton-on-Medlock, at a cost of £40,000, which is exclusive of the purchase of the site. The chairman of the committee said that they would serve three wards with a population of 72,000 and a rateable value of £330,000. The buildings are to be "palatial in character and extent," and "of a character unknown before." What this foreshadows it is not easy to divine, but presumably a good deal of money will be spent on decorations which will probably be vulgar and tawdry unless the promise is kept that they shall be "of a character unknown before." The *Manchester City News* objects to so much money being spent on these baths. The neighbourhood in which they are to be placed is in the main one of good houses and well-to-do people. It says: "No second-class baths will be required, because only first-class people will go. Washing-baths will not be wanted, because all the houses in the neighbourhood contain baths of their own. First-class Turkish and ladies' and gentlemen's swimming baths are to be provided. ...... The money would suffice to place six baths in as many poor and congested districts that urgently need them." This is quite true. There are already private and good Turkish and other baths easily accessible, and there seems no reason why there should be municipal competition. The really poor of the district will be much too shy and too dirty to enter these "palatial" baths. It has long been evident that as regards baths a large proportion of the members of the council, either from want of interest or want of thought, neglect the needs of the poor who want facilities for cleanliness for themselves and their children and are dazzled by the idea that they will have given their help towards the erection of a building "worthy of the city" and "of a character unknown before" They forget the thousands of women in the "slums" where a family is often crowded into one poor room who would be thankful to go themselves and to take their children to modest looking cottage baths but who would not enter "a palatial building." More attention should be given in this matter to the wants of those who form the majority of the population.

Manchester Southern Hospital: the Burns Cot.

At the Burns anniversary dinner of the Manchester and Salford Caledonian Association last year a very kindly suggestion was made by Mr. Peter Black. It was that as a memorial to Robert Burns a fund should be raised for the endowment of a cot in the Manchester Southern Hospital for Women and Children. This fund has now reached £350.

Stockport Isolation Hospital.

At the meeting of the Stockport Town Council on May 1st a scandal, as the report calls it, at the isolation hospital was discussed. The Sanitary Committee reported that a number of complaints had been made about the general administration of the hospital, and that the steward and matron and all the servants had resigned. It seems from the report that the patients and staff have been "boarded" with the matron, and the committee resolved that this system should be discontinued, that the committee itself should contract for the supply of food, and that the medical officer of health "cannot be exonerated from blame" for not keeping a more watchful eye on the feeding of the patients, for it was said that they had not had sufficient food. One of the most remarkable statements was made by an alderman who is reported to have said that "the matron had a right to make a profit out of the boarding of the patients, or else she should make an application for an increase of wages." It is easy to see how this system must almost inevitably lead to abuse. Nine pints of milk for 47 patients—two of them on "milk diet"! This cannot be called an extravagant allowance. When the medical officer asked the children one day at dinner-time if they wanted any more to eat 40 of the 43 present (17 girls and 23 boys) put up their hands. When they sent to the cook she replied that they had had "their allowances." The medical officer calculated that in 13 fortnights the milk was 1820 pints short, and no account had been kept of the stimulants used. At the inquiry of the committee the chairman informed the nurses that if they told the truth no action should be taken against them afterwards, but the alderman who approved of "farming" the patients "actually moved that the nurses should be asked to send in their resignations." They had complained of their food. No doubt, now that these abuses have been exposed to the light of day they will be remedied, but the moral may be drawn that all institutions require the watchful supervision of disinterested persons.

May 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Small-pox Epidemic.

THE condition of the city in reference to the occurrence of small-pox continues to improve. New cases are now only occasional events, and the total number of patients under treatment has fallen to nearly 100. An interesting official statement dealing with vaccination and revaccination in the city was made by the Lord Advocate in the House of Commons on May 3rd. From this it appears that practically the whole infant population is vaccinated as the normal and regular rule, and quite independently of the existence of small-pox. Thus in 1899 the total number of births was 24 247, and of this number, after deduction of those who died before the ordinary period for vaccination had expired, only 775 remained without satisfactory evidence in connexion with vaccination. Revaccination is in an entirely different position. Except when small-pox is present in the community it is almost entirely neglected, and it is only when the disease shows considerable activity that the practice becomes anything like popular. Thus in connexion with the present epidemic small-pox first showed itself in April, 1900, yet, as far as the official returns on the subject go, the numbers revaccinated for each period of four weeks were below 100 per 10,000 of the population above five years of age until the months of February, March, and April last, when they rose to 1740, 1244, and 1534 respectively. On the same occasion the Lord Advocate, in remarking on the misapprehensions which have prevailed regarding the severity of the outbreak, quoted figures to show that in the year terminating March 31st, 1901, the total number of cases had only amounted to 2·28 per 1000 whilst the deaths had been 197 out of a population of 750 000.

The Public Health of Glasgow.

A sub-committee of the Corporation of Glasgow has for some time been engaged in the consideration of a proposal to establish one or more municipal cemeteries. From a report recently presented to the town council it appears that such cemeteries are owned by 55 municipalities in England, by five municipalities in Scotland, and by one municipality in Ireland. With reference to the existing cemeteries in Glasgow, the report states that in one of these 36,331 interments have taken place in one small plot of ground during the last 15 years. The cost of lairs in various municipal cemeteries is also shown to be less than the charges in the Glasgow cemeteries. For these and other reasons the sub-committee recommends the town council to approve of the principle of establishing one or more municipal cemeteries in the city or immediate neighbourhood, and asks for powers to report upon the detailed arrangements necessary for carrying out the scheme. The consideration of the report will occupy the attention of the council at its next meeting. Councillor Dr. James Erskine has given notice of his intention to propose at that meeting a motion directing the health committee to consider and report upon the measures which can competently be taken by the corporation in the way of establishing in working-class districts one or more depôts for supplying wholesome prepared milk with a view to diminish infantile mortality.

Marine Biological Association.

In his inaugural address in connexion with the new teaching arrangements at the Millport Marine Station Sir John Murray, K.C.B., discussed the practical value of the scientific research work carried on at this and similar institutions and claimed that such work was essential for the material progress and welfare of the nation. In illustration of this position he referred to the *Challenger* expedition, the expenditure on which—a sum of nearly £200,000—it was sometimes reproachfully said had produced no corresponding economic result. As a matter of fact his own work on a small group of organisms had enabled him to point out that the rocks on a certain oceanic island were of great value; his report had led to the acquisition of this island by the British Government and within the next few years he believed that the commercial value of this one observation would more than meet the entire outlay on the whole of the expedition. Sir John Murray announced his intention to give three prizes of £50 each for the encouragement of work in biological science.

University of Aberdeen.

The prize presented by Lord Strathcona, Lord Rector of Aberdeen University, will, so far as the medical faculty is concerned, be awarded this year to the best thesis in the professional examination for the M.D. degree. The demolition of old buildings to afford the site for the new Greyfriars church in connexion with the extension of Marischal College has now been commenced.

May 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Branch of the National Association for the Prevention of Tuberculosis.

THE annual meeting of the Dublin Branch of the National Association for the Prevention of Tuberculosis was held on May 4th in the hall of the Royal College of Physicians of Ireland. His Excellency the Lord Lieutenant of Ireland was in the chair and in the course of the proceedings he delivered a most interesting address, in which he said that any discussion on matters affecting the health of the people of Dublin led to only one conclusion—namely, that the question of sanitation in Ireland required the gravest consideration from all Irishmen. He hoped that meetings such as that would induce the people to take a more serious view of their responsibility and of the measures which they should take in order to prevent the spread of a terrible scourge such as tuberculosis. His Excellency referred to the deep interest which His Majesty takes in the problem of the housing of the working classes and to the prominent place in the deliberations of the congress to be held in London in July which this subject will certainly occupy. He made a pointed allusion to the comparatively small proportions of the meeting which he addressed and said that he feared that it might be typical of a want of energy and determination on the part of the citizens of Dublin at large to support the operations of the association. His Excellency's address was, as usual, thoughtful and suggestive, and, moreover, humorous when he alluded to his own recent attack of influenza which the medical faculty had failed to stave off. The meeting was also addressed by the President of the Royal College of Physicians of Ireland, the President of the Royal College of Surgeons in Ireland, Mr. Justice Barton, the Registrar General, and Professor Antony Roche.

The Meath Hospital and County Dublin Infirmary.

The annual meeting of the life members and governors of the Meath Hospital took place on April 29th in the board-room of the institution. In the absence of Lord Meath the chair was occupied by Sir Percy Grace, to whom the general and medical reports of the hospital for the past year were submitted.

Royal College of Physicians of Ireland.

Sir Christopher Nixon, President of the Royal College of Physicians of Ireland, entertained a distinguished company at a collegiate banquet on the evening of April 29th. His Excellency the Lord Lieutenant of Ireland was unable, owing to indisposition, to be present.

Health of Belfast.

From March 24th to April 20th, 1901, there have been notified in Belfast 90 cases of typhoid fever, 60 of simple continued fever 39 of erysipelas, 21 of scarlet fever, 11 of diphtheria, 5 of croup, 4 of puerperal fever, 2 of small-pox, and 1 of typhus fever. In the same four weeks there were in Belfast 849 births and 755 deaths. There were 93 deaths from zymotic diseases, 100 from phthisis, and 289 from respiratory diseases. The annual death-rate from all causes was 27·4 per 1000, 3·4 from zymotic diseases, and 11·1 from chest affections. Two cases of small-pox occurred in barracks. The patients, who had caught the disease in Scotland, were removed promptly to the Union Hospital, and so far no other cases have occurred. It is said that some other cases of small-pox have been met with in the neighbourhood of Lisburn. In the discussion following the medical report at the meeting of the Belfast City Council on May 1st one of the speakers drew attention to the duplications of notifications of infectious disease and to the alleged fact that many medical men in large practices do not notify at all. The matter is to be inquired into.

Belfast Medical School: the Summer Session.

The summer session began last week both at the Royal Victoria Hospital and at Queen's College, Belfast, where classes are now in full work again.

The North Infirmary, Cork.

The annual meeting of subscribers to the above institution was held recently, and the report for the year 1900 was read by the honorary treasurer. The statement on the whole was a satisfactory one. The daily average number of beds occupied was 77. The cases of accident and emergency numbered 7520, and there were 21,853 attendances in the extern departments. With regard to the financial state of the institution it was pointed out that a special appeal had so far resulted in the receipt of £250, but on the other hand there had been a slight falling off in the subscriptions. The total expenditure was £3501 0*s.* 8*d.*, and at the end of the year the infirmary was in debt to the amount of £524 18*s.* 5*d.* The cost of maintenance per bed was nearly £46. The governors expressed their very high commendation of the services rendered by the medical, surgical, and nursing staffs during the year.

Hospital Saturday in Limerick.

A very representative meeting presided over by the Mayor was held in Limerick last week for the purpose of establishing a Hospital Saturday collection in aid of Barrington's, St. John's, and the Lying-in hospitals. The Mayor, in the course of his observations, mentioned that the debt of Barrington's Hospital was £12,000, while that of St. John's Hospital was £1500. The various speakers warmly commended the project and it was decided that the funds should be distributed as follows: one-fifth to the Lying-in Hospital and the remainder to be divided equally between the two other hospitals.

May 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical Application of Intra-spinal Injections of Cocaine

INJECTIONS of cocaine into the sub-arachnoidal spinal space, on the utility of which surgeons and accoucheurs are not agreed, are becoming more and more used in medical treatment. M. Marie and M. Guillain have reported a case in which an acute attack of lumbago was cured in eight minutes by an injection of five milligrammes of cocaine. It is true that M. Merklen and M. Rendu have observed the same results to follow injections of artificial serum or of distilled water while the use of cocaine in neuralgia of the hairy scalp and in a case of acute lumbar rheumatism has had no success whatever. M. Achard met with a striking success by the use of this method in a case of acute pain in a man suffering from zona of the abdomino-crural region, while in another case the effect was even more remarkable. The patient suffered from syphilitic myelitis and had for some years been subject to crises of painful priapism through which he had been arrested upon a charge of outraging public decency. The injection of one centigramme of cocaine entirely did away with the priapism and the pain. The patient remained well for a space of three weeks when he left the hospital. M. Sicard has just proposed an improvement in the method of administration which makes the operation much safer. He makes the injection at the level of the sacro-coccygeal articulation and so obviates any risk of wounding the cord. True surgical anæsthesia cannot be obtained in this way, but he has at once relieved cases of sciatica which were most resistant to ordinary treatment. By a somewhat similar method of treatment M. Debove has succeeded in relieving, for the moment, gastric crises in cases of tabes by simple lumbar puncture.

Ichthyol in Leprosy.

M. de Brun of Bayreuth has laid before the Academy of Medicine some remarkable results obtained by him in the treatment of tuberculous leprosy by ichthyol administered by the mouth. He began by daily doses of 30 centigrammes, but soon found that he could give five grammes at a sitting, which dose could easily be increased to eight or 10 grammes without bad results. After some months' treatment the tubercles became paler and flattened and the ulcerative rhinitis almost completely disappeared. Local applications of ichthyol gave no result and the drug was absolutely useless in the case of anæsthetic leprosy.

The Transactions of the International Congress of Medicine.

The publication of the Transactions of the International Congress of Medicine held at Paris is going ahead with unheard-of rapidity. The transactions of the congress held at Rome have only got as far as the second volume, those of the Moscow Congress are only just out but the Paris transactions will appear by the end of August—that is to say, within a period of one year. Volume I., containing the section of Neurology, was published in December, the volume on the Urinary Tract appeared on Jan. 15th, and that on Histology, Anatomy, and Physiology on March 10th. One volume will come out every 15 days The 17 volumes will contain, altogether 14 000 pages of text. This remarkable result does honour to the Librairie Masson which alone of French publishing houses could have carried such a colossal enterprise to a successful end. The success attained is due to the work having been divided up among various sections, each of which works as an independent body under a responsible secretary whose work has much facilitated that of the general secretary, M. Chauffard, and of the president, M. Lannelongue.

Murderous Attack on a Medical Man.

Dr. Monnier, surgeon to the hospital at Vaucluse, a man very highly esteemed in the district and mayor of the town, has been the victim of a homicidal attempt perpetrated whilst he was making his visit in the hospital. A patient who had been admitted with cancer of the tongue came up to him for the purpose of making a complaint, and suddenly, before anyone could perceive his intention, he plunged a knife into Dr. Monnier's breast and then killed himself on the spot with the same weapon. Dr. Monnier is still alive, but in a very serious condition. The patient, who knew that his disease was incurable, had for a good while shown signs of despondency, and at the same time was full of complaints against the surgeon who, he said, did him no good. It has since been ascertained that 10 years ago the man had some personal disagreement with Dr. Monnier in the course of an electoral contest.

May 7th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague.

CASES of plague continue to occur at Perth and Brisbane and the public in both cities are rushing to be inoculated with anti-plague serum. In Perth the supply of Haffkine's serum is running short. In New South Wales and Victoria strict precautions are being observed to prevent the introduction of the disease by sea, and destruction of rats is prosecuted with vigour. Up to date 12 cases have developed at Perth, two of which ended fatally.

Outbreak of Small-pox.

The quarantine regulations have once more failed to keep small-pox out of Australia, and as the means of communication between Australia and other countries increase and the time occupied in the voyage is decreased such failures will be more and more frequent In the present case the steamer *Euryalus* arrived in Melbourne from Calcutta on March 2nd, discharged her Melbourne passengers and cargo, and went on to Sydney, and thence to Newcastle. On March 13th one of the Melbourne passengers was discovered to be suffering from small-pox and was promptly placed in the sanatorium It was then found that when the *Euryalus* reached Adelaide one of the passengers was unwell, but the captain reported all well to the health officer, who, however, noticed the sick passenger, examined him, found his temperature normal, and did not regard the case as one of small-pox, although the patient had an eruption on his arms The vessel was accordingly cleared at Adelaide This passenger was with some difficulty traced to Sydney, where he was found to be still suffering from small-pox and was removed to quarantine. In the meantime he had been moving freely about both in Melbourne and Sydney. Most of the other passengers by the *Euryalus* have been traced and kept under observation and so far no other cases of small-pox have been discovered in Melbourne, but one case developed in Sydney. The greater number of the passengers by the *Euryalus* were vaccinated in Calcutta recently. The *Euryalus* was fumigated at Newcastle and detained under observation, but no cases having occurred among the crew she was released from quarantine on March 28th The Board of Health of Victoria are taking legal advice as to prosecuting the captain of the *Euryalus* for breach of the Quarantine Act

The Adelaide Hospital.

The dispute at the Adelaide Hospital has been settled at last Dr W Ramsay Smith, the resident physician appointed by the Government, has left for South Africa as medical officer to the fifth contingent and before leaving he tendered his resignation as physician to the hospital Dr. J C Verco and Dr. Hayward, the honorary physicians to the hospital at the time when the dispute began, will immediately take over Dr. Smith's beds, and arrangements are being made for the university staff to begin work at the hospital.

Site for the New Children's Hospital, Sydney.

Some time ago the Government of New South Wales provided a site for a new children's hospital Objection is now taken to the site that it is too difficult of access, and that it would cost from £3000 to £4000 to drain and to prepare the site for a hospital. The committee of the hospital have cast envious eyes on what they regard as an ideal site in the neighbourhood but which was not in the gift of the Government A deputation recently waited on the Colonial Secretary to ask permission to sell the site given by the Government and purchase the other which, it was understood, would shortly be for sale The Minister promised to lay the matter before the Cabinet The public has responded very well to the call for funds for the erection of the new hospital and over £10,000 have been subscribed already.

Prince Alfred Hospital, Sydney.

A deputation representing the board of directors of the Prince Alfred Hospital, Sydney, waited recently on the Colonial Secretary to ask him to provide the necessary funds (£40,000) for completing the original design of the hospital. This would be done by erecting two pavilions to accommodate 120 patients. It was pointed out that patients had daily to be refused admission to the already overcrowded hospital. The number of beds at present was 236, but only on nine days since the beginning of the year has the number of patients not exceeded this, rising as high as even 249 The Royal Commission on Public Charities reported that "any increase of hospital accommodation in Sydney should be in connexion with this institution; the space is ample, the site good, and the administrative buildings being already in existence the cost per bed of extra accommodation would be materially reduced." The Minister was sympathetic and assured the deputation that the Government would submit to Parliament in the next estimates a vote for £40 000 to build the additions to the hospital, and he quite appreciated the noble work which the Prince Alfred Hospital was doing

The Inebriates Act, New South Wales

The Colonial Secretary is considering the selection of a site for the necessary buildings for the purposes of the new Inebriates Act. One of the islands on the Parramatta river has been suggested as suitable

Death of Mr. W. Langford.

Mr. William Langford, M R C S Eng., died at Kyneton, Victoria, on March 21st He was born at Mysore, India, in 1831 and was educated at King's College, London He was for a time surgeon to the hospital at Coventry and then entered the service of the Peninsular and Oriental Steam Navigation Company He came to Australia in 1865 and commenced practice in Castlemaine and subsequently moved to Kyneton where he has since practised. He married a niece of Cardinal Newman and daughter of a well-known writer for the *Times* Mr Langford had literary tastes. He wrote a lengthy poem founded on a Sanskrit legend and published two novels entitled "Tifana's Revenge" and "Werona"

March 29th

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the examination for the degree of M C, Easter Term, the following candidate was successful —

W. D Harmer, M A., King's

At the third examination for medical and surgical degrees, Easter Term, the following candidates were successful :—

Doctor in Hygiene (D Hy)—Reginald Green, M D, B S., D.Hy

Bachelor in Medicine (M B)—Edmund Howard Barrett, M.R.C S., L.R.C P, St. Mary's Hospital; George Burrows Brown, College of Medicine, Newcastle-upon Tyne; Frederick Clarkson, St. Thomas's

Hospital; Charles Fisher, M.R C.S , L R C.P., St. Bartholomew's Hospital; James Willie Heslop, Richard Arthur Mills-Roberts, M.R C S., L.R C P., and Stanley Raw, College of Medicine, Newcastle-upon-Tyne; Thomas Basil Rhodes, Birmingham University; William Waters Stainthorpe, Junr., College of Medicine, Newcastle-upon-Tyne; Fred Stuart, M.R.C.S., L R.C.P., College of Medicine, Newcastle upon-Tyne, and St. George's Hospital; Alexander Minter Watts, M R C S., L R C.P., University College, London; Frederick Percy Wigfield, College of Medicine, Newcastle-upon-Tyne, and Reginald Worth, M.R C.S., L R.C.P., St. Mary's Hospital.

Bachelor in Surgery (*B S*)—Edmund Howard Barrett, M.R.C S., L.R C.P, St. Mary's Hospital; Frederick Clarkson, St. Thomas's Hospital; Charles Fisher, M.R.C S , L R.C.P., St. Bartholomew's Hospital; James Willie Heslop, and Stanley Raw, College of Medicine, Newcastle-upon-Tyne; Thomas Basil Rhodes, Birmingham University; William Waters Stainthorpe, Jun , College of Medicine, Newcastle-upon Tyne; Fred Stuart, College of Medicine, Newcastle-upon-Tyne, and St. George's Hospital; Alexander Minter Watts, M.R.C S., L R.C P., University College, London; Frederick Percy Wigfield, College of Medicine, Newcastle-upon-Tyne; and Reginald Worth, M R C S., L.R C P., St. Mary's Hospital.

Bachelor in Hygiene (*B Hy*)—George Whitson Middlemiss, M.B., B S Durh., and Duncan Macfadyen Millar, M.B., C.M. Glasg.

Diploma in Public Health (*D.P.H*)—Andrew Halliday, M.B., C.M. Glasg.; George Whitson Middlemiss, M.B., B.S. Durh , and William Henry Rowell, M.D., B.S , B.Hy. Durh.

UNIVERSITY OF EDINBURGH.—The following is the official list of passes at the recent first, second, and third professional examinations for degrees in Medicine and Surgery:—

First Professional Examination.—Francis Aitken, J. O. D. Allan, William Anderson, W. T. Archibald, Francis Baillie, M. M. Sujjad Beg, A. M. Black, Richard Bladworth, Thomas Campbell, John Chisholm, A. G. Cook, J. G. Craig, D. C. Crole, E. G. Deverell, Pollok Donald, G. T. Drummond, F. E Field, G. H. L. Fitzwilliams, O. M. Gericke, J. M. Grant, Thomas Grant, Charlotte R Greenfield, O. C. Greenidge, T. A. Gregg, John Grieve, J. D. Harmer, Ada A Hatchard, R. W. D. Hewson, Jane S Hogg, J. G. Hume, T. Scoresby Jackson, J. F. James, J. P. S. Jamieson, A. A. Jardine, Olive T. Leonard, John Lindsay, S. M. Livesey, W. L. Locke, F. J. Luck, William Lumsden, A. D. M'Callum, C. I. M'Farlane, James MacKenzie, A. C. M'Master, N. N. G. C. M'Vean, William Magill, Alfred Malseed, H. G. Marshall, William Martin, C. E. F. von Mengershausen, H. P. Milligan, C. E S Mitchell, J. S. Mitchell, Venancio Moralejo, H. B. Morris, G. P. Norman, H. J. Norman, G. O Norrie, Garfield Ormrod, W. J. Patterson, A. C. Pickering, Agnes E Porter, J. R. Robertson, W. D Sibbald, E. M. Simmers, Oliver Smith, S. A. Smith, W. T Smith, William Stenhouse, H. G. Sutherland, J. R. Tannahill, W. B. Tannahill, F. J. G. Tocher, A. N J. Vizarat, Frances M. Wakefield, R C. Walker, R. W. L. Wallace, H. E. A. Washbourn, J.S. R. Weir, Elsie B Wilkie, and R M. Wishart.

Second Professional Examination.—Daniel Allison, G. C. Anderson, J. A. Anderson, F. L. Atkinson, C. M. Begg, James Bentley, A W. Beveridge, T. C. Blackwell, William Blackwood, F. H. Borthwick, J. C. Boyd, Edith C. Brown, G. L. Brunton, G Macqueen Brunton, Angus Buchanan, H. H Bullmore, R A. Chambers, Kate J. S. Clark, Elizabeth L. Colby, A F. R Conder, C. H. Craig, R. W. Craig, C. S. Crichton, Sam Cunliffe, Henry Curwen, Arthur Dangerfield, H S Davidson, James Davidson, W. H. Davison, D. E. Derry, A C. Devereux, J. M. Dewar, James Donaldson, A. M. Dryden, G J. Farle, John Findlay, John Fortune, A C. Geddes, C. R. Gibson (with distinction), J. D. Giles, James Girdwood, Alexander Gray, M.A., H. W. Gush, A. A. Hall, M A. (with distinction), C. R F Hartley, George Henderson, R L Henderson, A E. Hodgson, A F. Hughes, Isaac Ivey, J. M. Johnston, R W. Johnstone, J. H. Kay, J. W. Keay, I. C. Keir, M. L. Ali Khan, J. M Kirkness (with distinction) L A. H. Lack (with distinction), F. W. Lundie, Hugh M'Calman, G. S. Mackay, T. H. Mackinnon, William MacLaren, J. B M'Neill, I. M. Macrae, P. W. Mason, A. S Millard, G. H. S. Milln, W. O. Morton, M A. (with distinction), Ernest Muir, C. H. Muller, H. L Munro, A E. Nalborough, M. Newton, Harry Overy, T. C. E. Parry, D. D. Paton, M.A., Thomas Peebles, J. A Pottinger, Julia L Pringle, J A. Raubenheimer, William Readman, Eva A. Robertson, Amy Robinson, Mabel Ross, J. A. Roux, N C. Rutherford, D. G. Addison Scott, G. H. Skinner, S. W. Smith, Eva M Snowball, Henry Speirs, Amelia Sutcliffe, J. M. Taylor, A R M. Thomson, Louis Turiansky, Robert Veitch, W. R. S. Watkins, G. J. Wentzel, D. H. Wessels, W. D. Wright, G. W. Young, and William Young.

Old Regulations—R. J. Irving, Harry Whittaker, and J. O. Williams.

Third Professional Examination—Lewis Anderson, R. G. Archibald, James Arthur, Mohomed Ashruff, Alexander K. Baxter, Breadalbane Blacklock, C. H. Bosenberg, J. R. Bosman, E. A. Braine, G. B. Brand, R D. Brown, W. A. Brown, Archibald Brownlie, D M. Callender, C. M. Campbell, M.A , B Sc., G. S. Carey, J. C. G. Carmichael, T. F. Cavanagh, A M. Caverhill, J. H. Connolly, T. M. Cuthbert, Maurice Davies, F. L Dawson, Jan Dommisse, C. B Drew, H. J. Dunbar, J. F. Duncan, John Dunlop, S A. Ellerbek (with distinction), J. S. Elliott, S. C. Ellison, A. N. Fell, Sydney Gilford (with distinction), Archibald Gillespie, D. P. Goil, Wilbert Goodchild, Thomas Gowans, Andrew Grant, J. P. Grant, B Sc., Mabel D. Gulland, J. F. Haegert, T. B. Hamilton, D J. Hamman, Howard Harding, Frances M. Harper, A. W. M. Harvey, A. W. Hauman, Henry Herd, M.A., Mathew Holmes, William Hume, R. C. Irvine, Harold Kerr, R. D. Kidd, James Kirkwood, H. A. Knight, Hermann Kramer, Vivian Langmore, Nora Lenwood, William Lillico, Duncan Lorimer, R. C. Low (with distinction), W. F. MacDonald, D. R. Macgregor (with distinction), Isabel N. M'Keand, William M'Lachlan, S. W. Maclean, R. P. M'Neil, C. E. Marshall, W. E. Marshall, J. K. Matheson, Paul Mathews, R J. Mayberry, A. M. Moll, J. H. Montgomery, S. A. Moore, A. E. Morton, P. H. Mules, R. S. Munro, D. N. W. Murray, William Newlands, T. H. Osler, Sophie Palmer, J. H. H. Pirie, B.Sc., Herdman Porter, W. G. Porter, B.Sc., Agnes M. Pringle, J. J. Redhead, A. B. dos Remedios, H. H. Robarts, A. B Ross, M.A., T. W. E. Ross, A. J. Rowan, R. E. Russell, C. W. V. Rutherford, James Scoble, J. S. Sewell, A. M. Sharp, M A., E. S Sharpe, C. J. Shaw (with distinction), Maurice Sinclair, W. F. Sincall, J. M. Smith, Robert Sproule, Elbert Steyn, H. M. Stumbles, G. L Thompson, Philip Vickers, D. L. Wall, B P. Watson, Philip Weatherbe, John Wier, S. A. K. Wilson, M.A., and E. E. Wood.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Karl Günther, *custos* of the Institute of Hygiene, has been promoted to an Extraordinary Professorship.—*Bologna:* Dr. Sanarelli has been appointed to the chair of Hygiene. Dr. Rovighi has been promoted to the ordinary Professorship of Medical Pathology.—*Bonn:* Dr. Rumpf, late of the Hamburg General Hospital, has qualified as *privat-docent* of Internal Medicine —*Halle:* Dr. E. Kromayer has been promoted to an Extraordinary Professorship of Dermatology.—*Heidelberg:* Dr. G. Port of Munich has been appointed Extraordinary Professor of Odontology.—*Leipsic:* Dr. Krönig and Dr. Menge have been promoted to Extraordinary Professorships of Gynæcology. Dr. E. Kruckmann has been promoted to an Extraordinary Professorship of Ophthalmology.—*Leyden:* Dr. von Hansemann of Friedrichshain has been offered the chair of Pathological Anatomy. He was for many years Virchow's assistant at the Charité.—*Marburg:* Dr. A. Buchholz, senior physician in the Clinic for Mental Diseases, has been promoted to a Professorship.—*Montpellier:* Dr. Planchon, Lecturer in the Pharmaceutical School, has been appointed to the chair of Materia Medica in the University.—*New York* (*Bellevue Hospital Medical College*): Dr. J. E. Weeks has been appointed to the chair of Clinical Ophthalmology in succession to the late Dr. Noyes —*Paris:* Dr. Béhal has been appointed Professor of Toxicology in the École Supérieure de Pharmacie; Mdlle. A. Wycrolkowska, Doctor of Medicine, has been offered the chair of Experimental Psychology in the Psycho-Physiological Academy.—*Rostock:* Dr. Graser of Erlangen has been appointed to the chair of Surgery in succession to Professor Garré who goes to Konigsberg.—*Strasburg:* Dr. Kümmel of Breslau, who had been offered the chair of Otology, has decided to retain his present post.—*Tübingen:* Dr. Bürker has been recognised as *privat-docent* of Physiology.—*Vienna:* Dr. Arthur Biedl has been promoted to an Extraordinary Professorship of General and Experimental Pathology. A "Third" Surgical Clinic has been established, the charge of which is to be given to Professor Hochenegg; Dr. Katz and Dr. Erben have been recognised as *privat-docenten* of Internal Medicine and Dr. R Savor as *privat-docent* of Midwifery and Gynæcology.—*Würzburg:* Dr. von Franqué, *privat-docent* of Gynæcology, has been promoted to an Extraordinary Professorship.

QUEEN'S COLLEGE, BELFAST.—At the class examinations held in the above college at the close of the medical winter session the following prizes were awarded: Zoology: James Stuart Dickey, Robert Jamison, Samuel John Graham, Charles Dowall Bell, William Andrew M'Kee, William James Leighton, and Andrew Leitch —Systematic Anatomy: senior, Henry Hanna, M.A., B.Sc., Thomas Lyle, Mary Evelyn Simms, Joseph Clarke M'Pherson, and Samuel Kirkpatrick Adams; junior, William James Wilson, William Henry Davis, and William Joseph M'Learn Baird.—Practical Anatomy: senior, Henry Hanna, M.A., B.Sc., John M'Clatchey, and Joseph Henry Thompson; second year, Thomas Lyle, Joseph Clarke M'Pherson, Malcolm Orr Wilson, Samuel Kirkpatrick Adams, and Daniel Gillespie; first year, William James Wilson, and John Stevenson O'Neill and Thomas M'Cann Phillips (equal). Physiology and Histology: senior, Thomas Lyle and Joseph Clarke M'Pherson; junior, William James Wilson and Malcolm Orr Wilson. Practical Physiology: Charles James Boucher, Samuel Kirkpatrick Adams, and Thomas Lyle. Practical Histology: Malcolm Orr Wilson, William Joseph M'Learn Baird, and Ernest Clements. Medicine: Sydney Herbert George Blakely, William Alexander Stoops, B.A., and Samuel Thompson Irwin, B.A Surgery: senior, Sydney Herbert George Blakely, and Samuel Thompson Irwin, B.A., and Walter Phillips, B.A. (equal); junior, Thomas Henry Suffern, James Hamilton Campbell, and Joseph Corker. Materia Medica: Joseph Henry Thompson, Thomas Dixon Liddle, and Thomas Killen. Midwifery, Gynæcology, and Diseases of Children: Samuel Thompson Irwin, B.A., Robert James Bethune, James Hamilton Campbell, Frederic William Stewart, B.A., and James Wallace Killen and Samuel Robert Hunter, B.A. (equal). Ophthalmology and Otology: John Matthewson Clements, Samuel Robert Hunter, B.A., Sydney Herbert George Blakely, and Frederic William Stewart, B.A.

Coal Smoke Abatement Society.—At a committee meeting of this society, held at 14, Buckingham-gate, London, S W., on May 1st, 83 smoke nuisances were reported by the society's inspector. Instructions were given that the reports should be forwarded to the borough councils of Hammersmith, Chiswick, Fulham, Barnes, Kensington, Acton, Shoreditch, Holborn, Willesden, Brentford, Port of London, Battersea, and City of Westminster, in whose districts the nuisances had occurred.

The Oxford Graduates' Medical Club and the Cambridge Graduates' Medical Club decided to hold their annual dinner together this year, and the meeting took place at the Cecil Hotel on Monday, May 6th, Sir William Selby Church, Bart., M.D., P.R.C P., being in the chair. 122 members of the two clubs attended. The chairman proposed only two toasts—viz., "The King" and "The Clubs." After these had been drunk the company adjourned to an adjoining room, where musical entertainment was provided by various members of the two clubs.

The late Mr. A. E. Watson.—Mr. Arthur Edmundstone Watson died at his residence, 8, Portland-place, Torquay, on April 26th, after a short illness, in his thirty-fifth year. The deceased was the son of the late Mr. John Watson of Paris, and received his medical education at the Middlesex Hospital, where he obtained several prizes and was awarded the Broderip Scholarship in Medicine and Surgery in 1888. In the same year he qualified as L.R.C.P. Lond. and M.R.C.S. Eng., and after being casualty house surgeon at Middlesex Hospital was appointed house surgeon at the Torbay Hospital, Torquay. He had only lately resigned this post and commenced practice in Torquay, having been quite recently appointed a member of the staff of the Torbay Hospital. Mr. Watson contributed several reports of cases to The Lancet in 1892, 1893, and 1896.

The Medical Officer of Health of the Gelligaer and Rhigos Rural District.—The parish of Gelligaer is situated within the Merthyr Union in South Wales and is one of the wealthiest districts in the whole principality, having an area of nearly 23 000 acres and a rateable value of over £105,000. It is a mining district and during the last 10 years the population has increased from 13,718 to 18,959. Just over a year ago the post of medical officer of health became vacant by the death of Mr. Dyke who lived not in Gelligaer but in the town of Merthyr, and Dr. W. W. Jones, also of Merthyr, received the appointment, the tenure of which is annual. The question of Dr. Jones's re-appointment was recently under consideration by the parish council who have decided to impose a condition not hitherto attaching to the position—viz., that the medical officer of health shall reside in the district itself. The members of the council spoke highly of the efficient manner in which Dr. Jones had performed his duties, but thought that the interests of the district required that the medical officer of health should be resident within it. The salary is £126 per annum. Dr. Jones has consented to carry on the duties pending the decision of the Local Government Board to whom the question has been referred.

Presentations to Medical Men.—At a meeting of the members of the Cambridgeshire Hospital, Wisbech, on April 2nd, Mr. Charles Herbert Gunson, M.B. Glasg., was, on the occasion of his marriage, the recipient of a writing table, bearing on a brass plate an appropriate inscription, which was subscribed for by the trustees, committee of management, honorary medical officers, and other officials.—On the distribution of the prizes at Hunslet, on March 21st, obtained by the members of the Steam Plough Works Branch of the St. John Ambulance Association, Mr. L. A. Rowden, M.B. Glasg., was presented with a silver matchbox from the members of the class in recognition of his first-aid instructions.—On March 28th Mr. Edward James Sheppard, L.R.C.P., L.R C.S Edin., was presented with a walking stick, suitably inscribed, from the members of the Park-place (Clifton) Evening Continuation Schools Branch of the St. John Ambulance class as a mark of their appreciation of his services as honorary lecturer.—Mr. Tom R. Taylor, B Sc., M.D. Lond, F.R C S. Eng., has been presented by the Hospital Saturday Fund Division of the St. John Ambulance Brigade and first-aid nursing classes with a cabinet, &c, as a mark of gratitude for his services during the past few years.—A large and representative meeting of the inhabitants of Newburgh and district, Fife, was held in the Public Hall, Newburgh, on April 27th, to present Mr. Thomas Niven, M.B. Glasg., J.P., with a testimonial on his attaining his semi-jubilee as a medical practitioner in Newburgh. Provost Anderson of that town presided. Mr. Cathcart of Pitcairlie, convener of the county, in making the presentation in the name of the subscribers, remarked that Dr. Niven had practically made one of the largest districts his own, and the testimonial, which consisted of a valuable silver salver and a cheque, was a testimony that the inhabitants with whom he had lived for the past 25 years highly esteemed him and appreciated his professional services.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Lunacy Bill for Ireland.

The Lord Chancellor of Ireland has introduced in the House of Lords a Bill to amend the law relating to lunatics in that country.

Cremation.

The Bill to enable burial authorities to establish crematoria is now in a favourable position for passage into law during the present session. It has passed through all its stages in the House of Lords and in the House of Commons, it has been read a second time, and has successfully emerged from the ordeal of examination by the Grand Committee on Law. In its present state the Bill provides that the plans of each crematorium shall be approved by the Local Government Board and that the working of the establishment shall be carried on under regulations prescribed by the Home Office. It expressly states that these regulations shall prescribe in what cases and under what conditions the burning of any human remains may take place, and also the forms of the notices, certificates, declarations, and registrations. When the Bill was before the Grand Committee on Law it was suggested that a special clause should be inserted to safeguard the interests of justice, but the Solicitor-General expressed the view that the Home Office regulations would be sufficient for this purpose.

HOUSE OF COMMONS.

Thursday, May 2nd.

Ophthalmia and Ringworm in London Poor-law Institutions.

Dr. Farquharson asked the President of the Local Government Board whether he would state the number of children in the metropolitan Poor-law schools, infirmaries, and workhouses who were [illegible]

Curious Question of Diagnosis.

Dr. Farquharson asked the President of the Local Government Board (1) whether his attention had been called to the fact that 47 children had been removed from the Forest-gate Poor-law schools to the fever hospitals of the [illegible] under the erroneous belief that they [illegible] ver; and (2) whether any of the childrer [illegible] when in the fever hospitals.—Mr. Walt[illegible] of the fact [illegible] formed that [illegible] children in [illegible] suspicious [illegible] hospital as cases [illegible] cases of scarlet fever. It ultimately appeared, however, that none of the children thus sent in April were, in fact, suffering from that disease. I am advised that any error which may have been committed in sending these cases to the hospital cannot with justice be attributed to any want of care or anything else than anxiety to do the best for the safety of the school As regards the last paragraph of the question, I understand that none of the children sent to the fever hospitals contracted scarlet fever there

Medical Treatment of Sailors.

Mr. Arnold-Forster, in reply to a question addressed to him by Mr. Knowles, said that it was not the practice in the navy to send sailors to their homes on sick furlough, as they were treated in naval hospitals. The Admiralty did not pay the fees of medical practitioners who might attend seamen taken ill while on leave, but an allowance of 2s a day was granted to the men to assist them in defraying the cost of board, lodging, and medical attendance.

State Inebriate Reformatories.

Mr. Ritchie announced that he had given his approval to plans for [illegible]

Mr. J. P. Farrell asked the Secretary of State for War whether he was aware that on the night of March 31st last Private Michael Lee, late of the Imperial Yeomanry, who was at present confined to bed in Netley Hospital suffering from fits, the result of injuries received in South Africa, was beaten by the night student in charge of his ward whilst suffering from a fit, and that this young student had given orders not to be disturbed whether any of those in his care were ill or not, and on being called by the nurse to see Lee who was ill said that when he had done with him the patient would have few fits and thereupon proceeded to beat him in such a manner that his face was almost unrecognisable for days after; could he state whether any inquiry was held into this case; and what was the name of, and the punishment awarded to, this student.—Mr. Brodrick replied: It appears from the medical and military inquiries which have been held that this was a case of hystero epilepsy and that the surgeon in-charge restored the patient to consciousness by slapping his face There appears to be no doubt that the treatment was unnecessarily violent and some swelling was caused and the surgeon has been censured by his superiors. The surgeon justifies the treatment as being necessary to rouse the patient from the fit and I therefore propose to take eminent medical advice before dealing with his case.

Friday, May 3rd.

Plague at the Cape.

Lord Stanley stated, in reply to a question, that the reports of the cases of plague among the troops only mention the locality in the following—viz, one at Hermon Camp, Paarl District, two at Green Point, Cape Town, and two at Cape Town. The total cases of plague among the troops up to date amount to 14 among European soldiers, 20 native drivers, and seven other employés.

Medical Volunteers at the Front.

Mr. Schwann asked the Secretary of State for War whether he was aware that Manchester furnished many volunteers from the Volunteer Medical Staff Corps and bearer companies of the 2nd, 4th, 5th, and 16th Volunteer Rifle Battalions, all of whom were attached to the Royal Army Medical Corps; and whether these medical volunteers could be sent home at once, as they had more than completed their year of service, and many were losing their appointments in Manchester owing to the prolonged delay in their return —Mr. Brodrick replied: As I have repeatedly stated to the House, special consideration has been, and will be, shown in individual cases of hardship reported to the Commander in Chief in South Africa by commanding officers I am not aware that the position of these medical volunteers is different from that of the other volunteers who undertook to serve for one year or to the end of the war.

Small pox Precautions in Glasgow

The Lord Advocate made the following statement on this subject—viz.—There are no statistics available giving the monthly number of primary vaccinations performed in Glasgow, but practically the whole infant population is vaccinated even where no small pox is prevalent. Thus, for the year 1899, which is the last for which the complete figures are available, the total number of births was 24,247, and of this number, *after deduction of those who died before the ordinary period for* vaccination expired, there remain only 775 cases unaccounted for, which again include children removed from the district who may have been vaccinated elsewhere Except when small-pox is present in the community it is impossible to get the population generally to have re*course to revaccination*, and as during the 12 months prior to the beginning of the present outbreak in April, 1900, there had been no cases of the disease in Glasgow, little revaccination was done except in the case of the staff of the fever and small-pox hospitals, the post-office, and the police Small-pox showed itself first in April, 1900. The only figures available at present are the vaccinations by the officers of the sanitary department and returns to the medical officer of health, which show that the numbers revaccinated for each period of four weeks were below 100 per 10,000 of population above five years of age till the months of February, March, and April last, when they sprang up to 1740, 1244, and 1534 respectively. I should like to add, as I think there has prevailed some misapprehension in the matter, that during the whole year since small-pox made its appearance—i.e., from April 1st, 1900, to March 31st, 1901—the total number of cases has only amounted to 2·26 per 1000 and the deaths have been 197 out of a population of 750,000.

Monday, May 6th.

Typhoid Fever among the Troops in South Africa.

Sir Walter Foster asked the Secretary of State for War whether he could state the number of cases of typhoid fever among the forces in South Africa, and the number of deaths for each of the months of January, February, and March of this year, and also the total number of soldiers invalided home from all causes during the same months, and the number of deaths during the voyage —Mr. Brodrick replied that the figures were as follows:—January, 2121 cases, 356 deaths; February, 2119 cases, 391 deaths, and March, 2018 cases, 313 deaths. The number of soldiers invalided home from all causes during the same months who had arrived home was 4803 and the number of deaths during the voyage was 17.

Tuesday, May 7th.

Sanitation of New Buildings in Rural Districts.

Mr. Walter Long announced in reply to a question that he is preparing a series of model by-laws with respect to new buildings in rural districts which will deal only with matters most in need of control for purposes of health. The series, he said, is intended as a guide to rural district councils wishing to make by-laws on the subject and will be specially applicable to places consisting of scattered dwellings.

The Education Bill of the Government.

At this sitting of the House Sir John Gorst explained and introduced the Education Bill of the Government. What it proposes is to set up a new education authority in each county and county borough which in the meantime shall have the care of secondary and technical education, but which ultimately shall also have the care of primary education. This authority is to consist of a committee of members of the county council and others, male or female, who are not members of the county council, and for the work of the committee the county council is empowered to levy a rate not exceeding *2d.* in the £. The Bill was formally read a first time.

ROYAL COMMISSION ON ARSENICAL POISONING.

Friday, May 3rd.

The Royal Commission on Arsenical Poisoning, which consists of Lord Kelvin (Chairman), Sir William S. Church, Sir William Hart-Dyke, M.P., Professor Thorpe, Dr. B. A. Whitelegge, and Mr. Cosmo Bonsor, with Dr. G. S. Buchanan of the Local Government Board as secretary, held another meeting to-day in the Westminster Palace Hotel, London, when it examined two more witnesses.

Sir H. W. Primrose, Chairman of the Board of Inland Revenue, was the first witness and in the course of his examination he said that his Board possessed considerable power over breweries. These had been given for the protection of the revenue, but some might conceivably be utilised for the protection of public health if Parliament should so provide. By the Act 43 & 44 Vict., c. 20, every brewer of beer for sale was required to take out an Excise licence (Section 10), and to make entry of his premises, &c (Section 22), by delivering to the revenue officer a statement signed by him of the description of his premises, and of every room, place, and vessel intended to be used by him for his business, specifying the purpose for which each room, place, and vessel was to be used. The officer was empowered (Section 29) to enter any part of the premises at any time either by day or night to take an account of the materials used or to be used in brewing, and of the worts and beer produced. The officer was also empowered (Section 26) to take samples of any worts, beer, or materials for brewing in the possession of the brewer By the Act 48 & 49 Vict, c 51 every brewer of beer for sale who used any description of sugar was required (Section 7) to keep it until used in a sugar store, and was prohibited from receiving sugar unless it was accompanied by an invoice from the seller containing the particulars thereof. The Commissioners of Inland Revenue were empowered to require by a notice served upon the brewer that an account of all sugar received should be kept and upon the notice being given the brewer was required to deliver to the officer of Inland Revenue all the invoices relating to sugar subsequently received. A brewer of beer for sale was prohibited (Section 8) from adulterating beer or adding any matter or thing thereto except finings for the purpose of clarification or other matter or thing sanctioned by the Commissioners of Inland Revenue. By the Act 51 & 52 Vict, c. 8, the Commissioners of the Treasury were empowered (Section 5) to prohibit by notice in the *London Gazette* the use in brewing of any substance or liquor of a noxious or detrimental nature, or which, being a chemical or artificial extract or product, might affect prejudicially the interest of the revenue. Under this power the use of saccharin in brewing was prohibited by notice in the *London Gazette* of May 18th, 1888. As regards the policy of utilising the Excise Department as a guardian of public health, the Board of Inland Revenue were of opinion that it would be necessary to confine their intervention within *narrow and well defined limits. The test for the sake of* public health was different from that applied for the purposes of public revenue. Therefore it would be an additional duty if the department had to test for soundness. He thought that the duty was one that would better be intrusted to the various localities It could not be said that the department had taken any definite action with reference to the recent epidemic except to test samples of wort and beer for arsenic and to repay the duty on contaminated beer which was on brewery premises and which was destroyed. The Board, of course, considered whether any preventive action could be taken by *them. But the facts connected with the epidemic were then*, and to some extent still were, obscure, and eventually it was decided, after conference with the Treasury and the Local Government Board, to await the result of the several inquiries which were instituted, more especially *that of the present Royal Commission.*

Dr. James Campbell Brown, professor of chemistry in University College, Liverpool, and Victoria University, and chief of the county laboratory, Liverpool, was the other witness examined. He presented to the committee the results of analyses of various substances for arsenic, among them the results of 890 samples of beer. Of 52 samples of beer accurately determined one contained as much as 1·3 grains of white arsenic per gallon and two as little as from 0·03 to 0·06 grain of white arsenic per gallon. 16 samples were approximately estimated to contain between one-half grain and one grain per gallon Of brewing sugars one black glucose contained nine and three-quarter grains per pound and another eight grains per pound, these being the highest proportions. 48 samples of malt had been analysed during three months from private sources. All except six contained arsenic in quantities varying from a minute trace up to a quarter of a grain per pound. The six samples of malt free from arsenic had all been brushed after they came from the kiln. Six additional samples of malt had been analysed in March. These showed a great improvement The largest quantity was 0·04 or one-twenty-fifth of a grain per pound, and two contained only the minutest trace—practically nothing. 19 samples of yeast were analysed, all of which (except one) contained a distinct trace of arsenic. The quantity in each was too small to be determined, but the average quantity in the 18 samples was found to be 0·015, or one sixty seventh of a grain per pound. Latterly 14 additional samples of yeast had been analysed, all of which except two contained similar quantities of arsenic He had analysed six samples of brown oil of vitriol obtained from Messrs. Bostock. The first when received on Nov. 27th, 1900, was clear and brown, but it was supersaturated with arsenic. It contained 2·6 per cent. of arsenious oxide. On standing in a cool place for some weeks, with occasional disturbance, it gradually deposited crystals on the sides and bottom of the bottle and when the clear decanted acid was analysed on Jan. 17th, 1901, it contained only 1·12 per cent. of arsenious oxide, the rest having been deposited in the form of prisms, presumably rhombic. When these crystals were placed under the microscope, moist with oil of vitriol as they were, and a drop of water was added to dilute the oil of vitriol, the crystals cleaved into octohedra with flat sides, while some dissolved in the hot acid. On leaving the crystals they gradually grew, especially on the flat sides, and in two hours they were large and perfect octohedra. Other samples analysed in 1901 contained 1·92 per cent. of arsenic, including crystals deposited, 2·36 per cent., 2·24 per cent., and 2·5 per cent. All selenium was removed, as well as other impurities, before weighing the arsenic. Every article contained selenium, but only in very small quantities The average was probably about 0·005 per cent. His search for selenium in the sugars was an after-thought, and it was not very perfect and he did not find it. He added a small quantity of selenium to a sugar and on analysing the sugar he found that. He did not wish to be positive about selenium in the sugars because his examination for it was not a crucial one. He would not be prepared to go into the witness-box and swear that there was no selenium in the sugars. The city of Liverpool was completely cleared of beer made from Bostock's sugar before Dec. 18th, and in the county of Lancaster *only* a few samples here and there were found after that date. But still arsenic did not disappear from the beer sold even by perfectly reliable houses whose [illegible] [illegible]ical In some instances [illegible] brewer in the midlands [illegible] as Liverpool yeast which had been [illegible] sugar Beer from the brewery before [illegible] proportion of hops was added, was found to be more arsenical than the finished beer. This was usually [illegible] was small, but yeast and hops [illegible] arsenical beer Very large quan[illegible] cells. In slight cases the ye[illegible] the beer was drained off were found to contain some arsenic even when the finished clarified beer as sold contained practically none. Hops were found to be free from arsenic, the exceedingly minute trace suspected in one case being too small to be identified. The arsenic was in all cases investigated clearly traced to the malt The malt used was found to contain more arsenic than the finished beer made from it. A sample of beer made from good malt which had been dried with the best fuel was found to contain as much as one twelfth of a grain of arsenic per gallon before racking. This whole brew was destroyed. Another sample was made from very similar malt but not analysed until it was ready for sale, and it contained only one-[illegible]

[illegible] known to be liable to contain arsenic, and to leave out of account all the other things, known or unknown, which were liable, or would in the future be liable, to be in some way contaminated with other things. Any new legislation should aim at securing immunity from contamination for all kinds of food and drink Considering the fact that the use of arsenical glucose was the result of combined ignorance and carelessness, that it was immediately stopped when discovered, and that it was not likely ever to occur again, and considering also that arsenic was exceedingly likely to get into beer from malt, and that, in fact, minute traces were very seldom absent, it would be vain to prohibit the use of [illegible] ing arsenication of [illegible] the use of sugars [illegible] supposed that the [illegible] both glucose and [illegible] and Drugs Acts [illegible] as they were de[illegible] They could not g[illegible] coke merchant or to the sulphuric acid maker, nor could they take samples of coke or of sulphuric acid even as they were delivered to the maltster or glucose maker In his opinion they ought to have this power. Legislation was necessary to make it compulsory for manufacturers to test every bulk or batch sent out of any article which was to be [illegible]

SATURDAY, MAY 4TH.

The Commission held another meeting to-day in the Westminster Palace Hotel, Lord KELVIN presiding

Mr. THOMAS WATSON LOVIBOND, managing director of the Newcastle Breweries, Limited, and ex-chairman of the Country Brewers' Society, was the first witness examined. He said that he looked upon sugars and other adjuncts as absolutely necessary for modern brewing. If they were properly chosen they improved the [illegible] in some cas[illegible] enabled at [illegible] than was t[illegible] weeks at t[illegible] they coul[illegible] adjuncts. [illegible] the very finest, English barley was not fitted for use by itself Therefore the English barley grower would not benefit by [illegible] Speaking on behalf of the trade, [illegible] [illegible] was constantly being made that [illegible] trade did not use adjuncts. It was [illegible] use of adjuncts was in a minority [illegible] a minority of numbers, because these 5000 publican brewers represented only 3·8 per cent of the total brewing materials used in England and Wales. It was the publican brewers who used brewing sugars to a very small extent, while few of the important brewers did not use them. In the case of his own company they had analysed very carefully all their materials and products and they had found arsenic only in one case, and that was in a sample of malt dust, which, of course, did not go into the beer. They used for drying the malt a high class of oven coke which was found to be free from arsenic. They had given up glucose for a good many years and the only adjuncts they now used were inverted cane sugar and maize grits They inverted the former by means of yeast and the latter by natural diastatic conversion They gave up using sulphuric acid because it was a dangerous and unpleasant material to have in a brewery and because they found a better method of conversion He quite admitted that makers of invert sugar [illegible] was made he never heard of any injury whatever arising from the use of malt and when the inquiries were instituted which led to the suspicion that malt might be a contributory cause of danger in the production of beer his firm at once submitted samples of malts and subsequently of cokes and coals for analysis. The opinion gaining ground that coal was a safer material to use than coke or a mixed fuel, they at once used coal only, which they had continued to do Witness submitted a statement which, he said, proved conclusively that coal might be regarded as the best and purest fuel at present.

Mr. LAWRENCE BRIANT, brewers chemist, London, said that since the end of November, 1900, he had examined for arsenic considerably over 2000 samples of beer and brewing materials. He was requested by the chemical manufacturing section of the Brewery Traders' Association to make inquiries on their behalf into the presence of arsenic in their manufactures and the precautions taken to prevent such contaminations With this object he had visited the works of the firms connected with the association which, whilst not including absolutely the whole of the firms supplying brewers with preservatives [illegible] method of analysis [illegible] also examined a [illegible] Marsh test he was [illegible] of arsenious [illegible] arsenic he meant [illegible] when operating [illegible]ation. The substances into which he had made [illegible] materials, antiseptics, finings, caram[illegible] foods. The hardening of the brewing waters was extensively carried out. The following materials were used, the proportions given being the maximum generally added—viz, sulphate of lime, 50 grains per gallon, sulphate of magnesia, 10 grains, chloride of calcium, 20 grains, chloride of sodium, 50 grains, potassium sulphate or chloride, 15 grains; and kainit, 50 grains. Excepting caramel, the largest amount of arsenic which could be introduced into beer by any of these substances which he had examined could be only 0·00002 of a grain per gallon The worst sample of caramel which he had examined could not introduce more than one-four-hundredth of a grain per gallon of arsenic. The yeast foods used by brewers were of two descriptions—phosphatic and nitrogenous. Phosphatic yeast foods consisted of the phosphates of potash and ammonia, in some cases mixed with malt, pea, or bean flour. The [illegible] amount of arsenic which was present in some was due to the difficulty [illegible] adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BAIN, JAMES GORDON, M.B., C.M.Glasg., has been re-appointed Honorary Medical Officer to the Wellington (Somerset) Cottage Hospital

BOWKER, C. V., M.B Syd., has been appointed Medical Superintendent, the Sydney Hospital, New South Wales, vice W. C. McClelland, resigned.

BOYD, JOHN J., M.B Glasg., D.P.H Camb., has been appointed Medical Officer of Health to the County Borough of South Shields.

BREWERTON, ELMORE, F.R.C.S Eng., has been appointed Ophthalmic Surgeon to the Metropolitan Hospital.

BRIERLEY, T. B., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Tattenhall District of Cheshire.

BROWN, GRANGER C., M.R.C.S., L.R.C.P.Edin., has been appointed Honorary Medical Officer to the Holloway and North Islington Dispensary, vice J. R. T. Conner, resigned.

BROWN, H. E., M.B., Ch.B. Glasg., has been appointed Assistant Medical Officer, Southstone Asylum and Poorhouse, Greenock, vice M. Macdonald, resigned

BUTLER, G. H., L.R.C P. Lond., M.R C.S., has been appointed a Member of the Southern Tasmanian Board of Dental Examiners.

CARGILL, W. D., M.B , M.Ch. Syd., has been appointed, *pro tem.*, Medical Officer at Roma, Queensland.

CHESSON, HERBERT, L R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Superintendent to the Hospital for the Insane at Goodna, Queensland.

COAD, S. A., L R.C.P. Lond , M.R.C.S., has been appointed Medical Officer for the North District of Luton.

CORBIN, A. G., M.B. Syd., B Sc., has been appointed Senior Resident Medical Officer, Sydney Hospital, New South Wales.

CREED, J. M., L.R C.P. Edin., M.R.C.S., has been appointed a Trustee of the Public Library of New South Wales.

DODS, J. E., M.B , B S. Edin., has been appointed, *pro tem.*, Health and Medical Officer at Brisbane, also Visiting Surgeon to the Prison at Brisbane, the Penal Establishment at St Helena, the Fortitude Valley Police Gaol, the Dunwich Benevolent Asylum, and the Lock Hospital at Brisbane.

FENDICK, MAUDE E., L.S.A., has been appointed Assistant House Surgeon to the North Riding Infirmary, Middlesbrough.

FINLAY, WILLIAM, M.D., L.R C.P., L.R.C.S. Edin., has been appointed Officer of Health for the Shire of Tungamah, Victoria, Australia.

FOX, J. R., M.B Melb , has been appointed Public Vaccinator for Stawell, Victoria, Australia.

GMELIN, O. F., M.D. Leipz., has been appointed Officer of Health for the Shire of Eltham, Victoria, Australia.

GROSVENOR, RANDOLPH L, B A. Cantab , L R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician to the Chelsea, Brompton, and Belgrave Dispensary, Sloane-square, S.W.

HEDLEY, W. T., M.B , C M. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Hallaton Rural District of Leicestershire.

HILLYAR, CECIL BISSHOPP, L R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Honorary Surgeon to the Wellington (Somerset) Cottage Hospital.

HUMPHRY, ERNEST, L.R C.P. Lond., M.R.C.S., has been appointed Visiting Medical Officer to the Townsville State Orphanage, Queensland

JAMIESON, SYDNEY, M.B., Ch. M. Edin., L.R.C.P. Lond , M R.C.S., has been appointed Lecturer on Pathology at the University of Sydney, New South Wales

JONES, WILLIAM WATKINS, M.D., C.M. Edin., D.P.H. Cantab., has been re appointed Medical Officer of Health for the Gelligaer and Rhigor Rural District Council, South Wales.

JONES, W. W. S., L K.Q C.P. Irel., L.R.C.S., has been appointed Vaccinator for Glamorgan, Tasmania.

LEIGH, A., L.R.C P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Malpas District of Cheshire.

LONERGAN, T. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Officer of Health to the Southern Cross Local Board of Health, West Australia.

MALIN, J. W., B.A., M.B., B C., has been appointed Casualty House Surgeon to the General Hospital, Bristol.

MARTIN, A. F., M.B , Ch.B. Vict., has been appointed Assistant House Surgeon to the General Hospital, Bristol.

MATHEWS, C., M.R.C.S., has been appointed Medical Officer for the Atherington District by the Barnstaple Board of Guardians, vice F. T. Andrews, resigned.

MEREDITH, JOHN, M.D Edin., L.R C.S., has been re-appointed Honorary Medical Officer to the Wellington (Somerset) Cottage Hospital.

MINCHIN, E J., L K.Q.C.P. Irel., L.R.C.S., has been appointed Public Vaccinator for Portarlington, Victoria, Australia.

MORETON, T. W. E., L R.C.P. Lond., M R C S., has been appointed Certifying Surgeon under the Factory Acts for the Tarvin District of Cheshire.

OPIE, EDWARD AUGUSTUS, M.B. Durh., M.R.C.S., has been re-appointed Honorary Medical Officer to the Wellington (Somerset) Cottage Hospital.

O'REILLY, V., M.B., B.Ch. Irel , has been appointed Certifying Surgeon under the Factory Acts for the Civil Parish of Parbold, in the Wigan District of Lancashire.

PENNY, H. J., L K.Q C.P. Irel , L R C.S., has been appointed Vaccinator for Scottsdale, Tasmania.

POLLARD, W. R, M.R.C.P. Edin., L.R.C.S. Irel., has been appointed Medical Officer and Public Vaccinator, No. 2 District, Blackburn Union.

PRAAGST, G. D., M.B. Melb , has been appointed Public Vaccinator for Murchison, Victoria, Australia.

PRENDERGAST, J. J., M.D. Irel., L.R.C.P. Edin., M.R.C.S., has been appointed Vaccinator for Kelly Basin, Tasmania.

PRING, ARTHUR, L.R.C.P. Lond., has been appointed Medical Officer at Beaudesert, Queensland.

READ, CLARENCE, L.R C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer, North Shore Hospital, Sydney, New South Wales.

RENTON, M. W., M.B , C.M. Aberd., has been appointed Medical Officer with the Medical Corps in South Africa.

ROE, JAMES M., M.B. Syd., has been appointed Medical Officer at Mareeba, Queensland

SAIGOL, R. D, L M. & S. Punjab, L R.C.P. & S.E., has been appointed House Surgeon to the Birmingham and Midland Eye Hospital.

SKINNER, G. H., L.R C.P. Lond., M R.C.S., has been appointed Vaccinator for Gormanston, Tasmania.

SPRING, WM A., M.B., Ch.B. Melb., has been appointed Officer of Health for the Shire of Traralgon, Victoria, Australia

STACY, H. S., M.B , Ch.B. Syd., has been appointed Resident Pathologist, Sydney Hospital, New South Wales.

STRAHAN, E A., M.B. Melb , has been appointed Public Vaccinator for Korumburra, Victoria, Australia.

THOMAS, G. H. W., L R C.P. Lond., M.R.C.S., has been appointed Medical Officer at Chillagoe, Queensland.

TRENOW, N. A. A., L R C.S Irel., L.S.A. Lond., has been appointed Medical Officer at Croydon, Queensland.

WILKINSON, W. C., M.D. Lond., M R C.P. Lond., M.R.C.S., has been appointed Lecturer on Medicine at the Sydney University, New South Wales.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNWOOD HOUSE HOSPITAL FOR THE INSANE, Gloucester.—Junior Assistant Medical Officer. Salary £150 per annum (rising to £170) with board, &c.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary at rate of £80 per annum, with board, lodging, and washing provided.

BETHLEM HOSPITAL.—Two Resident House Physicians for six months. Honorarium at the rate of £12 12s. each per quarter, with apartments, board, and washing.

BIRKENHEAD UNION.—Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

BIRMINGHAM GENERAL DISPENSARY.—Resident Locums for two to three months. Terms 4 guineas per week, with furnished apartments.

BOROUGH OF HAMPSTEAD.—Medical Officer of Health. Salary £600 per annum.

BOROUGH OF SOUTHEND-ON-SEA.—Medical Officer of Health. Salary £400 per annum, rising to £500 per annum.

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.

BURY INFIRMARY.—Senior and Junior House Surgeon. Salary, Senior £110, Junior £90, with residence and attendance.

CHELTENHAM GENERAL HOSPITAL.—Junior House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £110 per year, with board, apartments, and laundress.

CHORLTON UPON-MEDLOCK DISPENSARY, Manchester.—Resident House Surgeon, unmarried. Salary £130 per annum, with furnished rooms and attendance.

COUNTY ASYLUM, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary £150 per annum, increasing to £250, with board, apartments, and washing.

COUNTY BOROUGH OF SOUTHAMPTON.—Assistant Medical Officer of Health. Salary £150 per annum, with residence and board.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician for six months. Honorarium £25, with board, residence, &c

GENERAL INFIRMARY, Leeds.—Resident Obstetric Officer for six or twelve months. Also House Surgeon for twelve months. Also House Physician for six months. Board, lodging, and washing provided in each case.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley.—Junior Assistant Medical Officer. Salary £120 a year, with rooms, board, laundry and attendance.

GREAT NORTHERN HOSPITAL, Holloway-road, N.—Casualty Officer for six months with eligibility for re-appointment. Salary at the rate of £52 10s. per annum.

GROVE HALL ASYLUM, Bow, London, E.—Junior Assistant Medical Officer. Salary £120 a year, with board, apartments, attendance, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £60, with board and lodging.

JARROW MEMORIAL HOSPITAL.—House Surgeon, unmarried.

KENT COUNTY OPHTHALMIC HOSPITAL, Maidstone.—House Surgeon. Salary £100, with board and lodging.

LIVERPOOL HOSPITAL FOR CONSUMPTION.—Non-resident Medical Officer. Salary £70 per annum.

LIVERPOOL STANLEY HOSPITAL.—Third House Surgeon. Salary £70, with board, residence, &c

METROPOLITAN ASYLUMS BOARD.—Six Assistant Medical Officers, unmarried, at the Fever and Small-pox Hospitals. Salary £160 per annum, rising to £200, with board, lodging, attendance, and washing.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £80 per annum, with board, attendance, and washing.

NEW HOSPITAL FOR WOMEN.—Two Resident Medical Officers; also a Clinical Assistant and a Pathologist. All females.

NORTHAMPTON GENERAL INFIRMARY.—Honorary Ophthalmic Surgeon. Also Honorary Assistant Surgeon.

NORTH LONDON HOSPITAL FOR CONSUMPTION, Hampstead.—Junior Resident Medical Officer. Honorarium, £60.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer. Also Assistant Resident Medical Officer, both for six months. Salary at the rate of £50 per annum, with board, residence, and washing.

NOTTINGHAM GENERAL INFIRMARY.—Senior Resident Surgeon. Salary £200 per annum, increasing by £15 every year. Also two Assistant Resident Surgeons Salaries £160 per annum each, increasing by £10 every year, furnished apartments, attendance, light, and fuel. Unmarried.

PARISH COUNCIL OF APPLECROSS, Loch Torridon District.—Medical Officer and Vaccinator. Salary £95, free house accommodation and other emoluments.

PARISH OF FULHAM.—Second Assistant Medical Officer. Salary £80 per annum, with board, furnished apartments, and washing.

PARISH OF ST. MATTHEW, Bethnal-green.—Clinical Assistant, unmarried, for the Infirmary at Cambridge-road, N.E., for three months, with possible extension. Salary at the rate of £80 per annum, with board, lodging, and washing.

QUEEN'S CENTRAL HOSPITAL, Cradock, Cape Colony.—House Surgeon and Secretary, unmarried. Salary £150 per annum, with board. lodging, and washing.

[illegible] Assistant Medical Officer. [illegible] nd washing. [illegible] House Surgeon for [illegible] Salary at the rate [illegible] ary £60 per annum, with board, lodging, and washing. Also Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing

ROYAL FREE HOSPITAL, Gray's Inn road, W.C—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing

ROYAL HALIFAX INFIRMARY.—Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing

ROYAL SEA BATHING HOSPITAL, Margate —Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, West Strand, W.C.—Clinical Assistants for six months

ST. MARYLEBONE INFIRMARY, Notting hill, W.—Second Assistant Medical Officer. Salary at the rate of £80 per annum, with board, &c.

SHEFFIELD ROYAL HOSPITAL.—Junior Assistant House Surgeon, unmarried Salary £50 per annum, with board (exclusive of wine and beer) and lodgings.

SOMERSET HOSPITAL, Cape Town —Senior Resident Surgeon. Salary £400 per annum, rising to £500, quarters and rations. Free passage to Cape Town.

STOCKPORT INFIRMARY —Assistant and Visiting House Surgeon. Salary £70, with residence, board, and washing Also Junior Assistant House Surgeon for six months. Salary at rate of £24 per annum, with board, washing, and residence.

THE CHIEF INSPECTOR OF FACTORIES gives notice of Vacancies for Certifying Surgeons under the Factory Acts at Elgin, in the county of Elgin, at Holyhead, in the county of Anglesey; at Brownhills, in the county of Stafford, at Crosshills, in the West Riding of the county of York; and at Darvel, in the county of Ayr.

THROAT HOSPITAL, Golden square, W.—Junior House Surgeon (non resident) Salary at the rate of £100 per annum and lunch daily.

TOWCESTER UNION.—District Medical Officer and Public Vaccinator. Salary £60 per annum, with allowances

WEST HAM BOROUGH ASYLUM —Senior Assistant Medical Officer. Salary £200, rising by £25 annually to £250 Also Junior Assistant Medical Officer, salary £150, rising by £25 annually to £200. Board, furnished apartments, and washing provided.

WEST HAM HOSPITAL, Stratford, E —Junior House Surgeon. Salary £75 per annum, with board, residence, &c.

WESTON-SUPER MARE HOSPITAL AND DISPENSARY —Medical Officer. Salary £100 per annum, with board, lodging, and washing.

WREXHAM INFIRMARY.—House Surgeon Salary £100 per annum, with board and washing.

Births, Marriages, and Deaths.

BIRTHS.

DEVEREUX.—On May 5th, at North House, Tewkesbury, the wife of William C. Devereux, M A., M B, of a daughter.

FEGAN—At Old Charlton, Kent, the wife of R. Ardra Fegan, M R.C S., L.R C P., of a daughter.

FITCH.—On April 29th, at Church Gate House, Chaddesley Corbett, Kidderminster, wife of Dennis Fitch, M.R.C.S, of a son.

MAWBY—On April 21st, at Mow Fen Hall. Littleport, the wife of F. Willders Mawby, Surgeon, of a daughter

MERCER.—On May 3rd, at Waterloo-road South, Wolverhampton, the wife of W. Stainton Mercer, M.R.C S, L.R.C.P. Lond., of a daughter.

PRALL.—At Rawalpindi, Punjab, India, on the 24th of April, the wife of Captain C. B Prall, Indian Medical Service, of a daughter.

RITCHIE.—On May 7th, at Beaumont-street, Oxford, the wife of James Ritchie, M.D, of a daughter.

MARRIAGES.

HACKNEY—WATTS.—On April 30th, at the parish church, Bromley, Kent, Alfred Clifford John Hill Hackney, L.R.C.P. Lond., M.R.C S., of Hythe, Kent, to Ellen Lilian, elder daughter of James Watts, Bromley, Kent.

HUTCHINSON—WALLEY—On April 30th, at St. Matthew's Church, Oakley square, N W [illegible] to Constance E. [illegible] Principal of the [illegible]

MORITZ—BENNETT.—[illegible] Moritz, M B. Ca[illegible] Highgate, to Co[illegible] of Avenue-road, [illegible]gate, N.

PRESTON—BOWKETT—On May 8th, at Emmanuel Church, West Hampstead, by Rev E. W. Pownall, M A., Francis H. Preston, M.A., M R.C.S, of Plumstead, to Hilda E Bowkett, daughter of the late Thos. E. Bowkett, M.R.C.S

DEATHS.

HARTREE.—At Cranmer-road, Cambridge, John Penn Hartree, M.A., M.D, aged 57

WALLIS—On May 6th, at High-street, Colchester, William Beale Wallis, Brigade Surgeon late 74th Highlanders, aged 71.

WATTS—On May 5th, at Shanklin, the Rev. Ernest Henry Richmond Watts, M.A., M B Cantab., Assistant Master St. Paul's School, of Russell-road, Kensington, aged 41.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

UNQUALIFIED MIDWIFERY.

THE body of a woman named Esther Cain was interred in Thornley (Durham) churchyard on April 20th last, the certificate being signed by "W. H. Ryott" and the cause of death specified as "parturition collapse" An order for disinterment, however, was received last week and an inquest was held by the coroner, Mr. Maynard, subsequently to a post mortem examination conducted by Dr. Hugh Russell of Trimdon Grange, Mr. J Arthur of Wingate, and Mr. G. C. Murray of Durham, the last-named gentleman acting on behalf of Ryott. At the inquest the husband of the deceased woman, an overman, stated that his wife was 35 years of age and the mother of nine children. Early on the morning of April 17th she sent witness for Mr. Ryott to attend her confinement and that gentleman came back and forward the [illegible] obtained, but between two and three o'clock on the morning of the 18th they told him to go for more assistance He went for another practitioner, but upon returning with that gentleman his wife was dead A fortnight or three weeks before, when the deceased chose Mr. Ryott to attend her witness warned her to be particular and to ask him about his qualification. Ryott told her that he was qualified to sign any paper.—Margaret Calvert, a neighbour, said that on the night of the 17th the deceased asked Ryott to give her chloroform, but he said that he dare not unless someone else was present to assist him in administering the anæsthetic. The deceased next asked Ryott to use instruments and he did so, but they were too short. Witness could not say if the longer instruments sent for were ever used. About 2 A.M. on the 18th Ryott again went for the practitioner who first came to his assistance. The two were with the patient about 20 minutes and then they left. Shortly after the deceased gave a shout, gnashed her teeth, and expired During the day she only had a few drops of tea. Ryott gave her a black liquid several times which seemed to ease the pain and he also administered a white powder which he said was to make her sleep. They did not notice any bleeding until after the short instruments were used and then it was very slight.—Dr. Hugh Russell deposed that he made a post-mortem examination on April 25th, assisted by others. The body was well nourished The left eye was slightly congested and there was a redness below both eyes. The breasts contained milk. The child was found to be a female. There were marks of compression upon the chin, the mouth, and the upper part of the chest, while there were two bruises on the back and side of the head an inch square. The inner part of the scalp was also bruised and the brain was soft. There were signs of considerable pressure on both the upper and lower limbs. In his opinion the woman's death was due to uterine rupture, and the signs of strong compression on the face and chest of the child led to the conclusion that the rupture was caused spontaneously. The fracture of the child's skull was due either to instruments or to pressure of the fingers He himself would have delivered the deceased long before death had occurred and her life would have been saved as well as that of the child in all probability. There was incapacity in the delivery of the woman and the long delay was the cause of death. She ought to have been safely delivered before noon on the 17th The child, he thought, had not water on the brain and she died shortly before the mother. Under the circumstances to give ergot of rye was most improper and when the deceased asked for chloroform it was a right and proper thing for her.—Mr. James Arthur corroborated the previous witness. Roughly speaking the patient had been left undelivered 12 hours longer than she ought to have been. In answer to the solicitor appearing on behalf of Ryott, witness said that there would be some difficulty to an ordinary medical man in the case.—Mr George Campbell Murray of Durham, called as a witness for Ryott, agreed with the evidence of Dr. Russell and Mr. Arthur, except that he was of opinion that there was hydrocephalus. He thought that the mother's life might have been saved had it been known that hydrocephalus was present.—An hour and three-quarters deliberation resulted in the jury returning the following verdict: "That the said Esther Cain came to her death by not being delivered of a female child through an error of judgment, want of skill, and neglect in not calling in a medical man sooner, but not sufficient to find William Harry Ryott guilty of manslaughter; but we are unanimously of opinion his practising in this way should be at once abandoned."

CHILDREN AND ALCOHOL.

THE terrible evils resulting from the alcoholic habit being acquired by children were strikingly exemplified in a letter addressed by Sir Thomas Barlow to the members of the United Kingdom Band of Hope Union and read at their recent meeting held in Exeter Hall. As Sir Thomas Barlow truly said, it is immensely difficult to give statistics proving that there is an appreciable amount of actual disease caused in children by the administration of alcohol. But it is easy to give illustrations showing that this does occur and the most notable example quoted by Sir Thomas Barlow was that of an infant who died when she was 12 months old. She was the subject of gin-drinker's liver in the most aggravated and typical form. The mother had given this child small quantities of gin and beer for a considerable part of her short life. Not the least interesting portion of Sir Thomas Barlow's letter was the explanation which it contained of his views on the question of heredity in alcoholism. It has been lately maintained that alcoholism and alcoholic habits are not in a true sense hereditary. But even if they are not handed on by direct transmission it was surely a matter of common experience that in some families one member after another succumbed to alcoholism. If this was brought about by the bad example of the parents and by habits of "tippling" induced in early life in a household where drinking was common the net result was just as disastrous as if it were a specifically inherited tendency. Nobody would deny the terrible risk of alcoholism in families where the different members manifested some form of defective nerve control, as, for example, perversion of moral sense, or eccentricity of behaviour, or actual insanity or hysteria. Dr. W. J. Collins, who was the chairman of the meeting, said that the London County Council had in spite of opposition persisted in a policy of temperance and had endeavoured to dissociate enjoyment, recreation, and amusement from the possible dangers of the drink traffic. In dealing with the question of the monopoly of drink he thought that the justices of the peace had entirely failed to do their duty. Mr. A. Pearce Gould considered that not only did alcohol find no place in the proper dietary, home life, and training of a child, but that it was distinctly harmful. If they were to keep in view the rearing of a strong race they must put alcohol away. Professor Sims Woodhead, writing from Cambridge, pointed out how alcohol, when acting on fully-developed tissues, produced sufficiently dire results, but that its effects on the actively growing and developing tissues of a child were most disastrous. The child who was taking alcohol could never be in perfect health. Amongst the speakers at the meeting were Mr. W. McAdam Eccles and Dr. T. Rushbrooke.

SEBORRHŒA.

To the Editors of THE LANCET.

SIRS,—May I ask advice as to how to treat a typical case of loss of hair with much formation of scurf and a dry scalp? My patient has persevered for weeks with a lotion which I ordered him (two grains of resorcin, five minims of castor-oil, and one ounce of rectified spirits of wine), and his scalp must by this time be thoroughly aseptic, but the scurf is as plentiful as ever.

I am, Sirs, yours faithfully,

May 8th, 1901. S.

LIFE AND WORK IN THE TROPICS.

IN an address delivered at the Church Missionary House on Feb. 22nd and published in the May number of the *Church Missionary Intelligencer*, Dr. Herbert Lankester has offered a few suggestions founded on his experience gained during many years connexion with the work of foreign missions. He reminded his hearers that with the exception of North Japan and North-West America all the Church Missionary Society's stations were situated in tropical or sub-tropical regions and under these conditions the work entailed much train, both physical and mental. The physical difficulties were connected with the high temperature, the unaccustomed food, and the special tropical diseases, of which he instanced malaria, dysentery, sprue, and cholera. Mental breakdown, manifested by loss of memory and inability to think, was unfortunately too often met with; the causes were overwork and responsibility, home sickness, contact with suffering, and, especially among ladies, the dread of a language examination. He assured his audience that a spirit of devotion counted for much in the preservation even of bodily health, and in addition he advised them when in the tropics to take plenty of exercise; to sleep with open windows; to have a cold, or at any rate a relatively cold, bath every morning if possible; not to study when tired; to go to bed early and to get up early; to eat simple food taken at regular meals; to learn to cook; to avoid worry and hurry; and to cultivate a useful hobby, such as photography or carpentry.

"THE EFFECTS OF THYROIDIN."

To the Editors of THE LANCET.

SIRS,—"K. E. M." gives the symptoms of a case in THE LANCET of April 27th, p. 1250, as a result of excessive doses of thyroidin. I suffer from identical symptoms and I did not take a single molecule of thyroidin in my life. I had dysentery followed by internal hæmorrhoids and prolapsus ani to an increasing extent. I took strychnia for some time until the smallest dose would produce spasms of the diaphragm and facial muscles. The smallest quantity of alcohol, even that in a bottle of ginger ale, produces neuralgic pains in the legs, especially in the left, and singing in the ears; I am prone to the tottering gait and great pains in the lower limbs in the evening after walking, becoming severe as I lie on a sofa or bed. I had the prolapsus operated on successfully, and still the symptoms continue. I find five grains of Dover's powder and five grains of antipyrin at night give relief. Bromide makes me worse though giving evanescent ease. I, too, increased in weight from 11 stones to 13 stones 5 pounds, and reduced it by walking to 12 stones. I attribute the affection to congestion of the nervous system. I suffer from intermittent heart and sleeplessness. Digitalis, strophanthus, and ext. ergotæ, guttæ duæ of each, have a beneficial effect.

I am, Sirs, yours faithfully,

West Kingstown, May 2nd, 1901. JOHN ROCHE, M.D. R.U.I.

MILITARY MEDICAL OFFICERS' UNIFORM.

DURING the eighteenth century the organisation of the military medical department was the subject of various royal ordinances in France, but it was not until 1757 that Louis XV. granted the officers a distinguishing uniform. According to Dr. G. Fargin, who discovered his authority in the Nancy library among the manuscripts which were bequeathed to that institution by M. Guerrier de Dumast, the original *arrêté* communicated to the army was couched in the following terms:—

> "On the account which I furnished to the King of the representations made to me by M. de la Martinière and by the Sieur Desports, surgeon-major of the army of Westphalia, concerning the necessity of giving a uniform to the surgeons employed in the army, to the end that they may be recognised on the day of battle and under other circumstances when there may be urgent need of their services, His Majesty desires that they should cause one to be made in conformity with the attached *mémoire*. I pray you to give them your orders on that and to inform the commandants of regiments with the army in Westphalia of what has been ruled for their surgeon-majors. It is necessary that the garments should be of the colour of the patterns which I send you, so that they may not be like those worn by Commissaries and officers of the Line.
>
> I am very perfectly, Monsieur, your very humble and very obedient servitor, R. DE ROYER DE PAULMY."

The *mémoire* alluded to, which is endorsed "Fait à Compiègne, le 15 Juillet, 1757," contains explicit instructions regarding the confection of the surgeon's uniform. The coats were to be *gris d'épine* in colour with red facings, their shape was to be *en surtout*, and they were to be fitted with long pockets. The breeches and vests were to be red, while all buttons were to be of gold thread. Surgeon-majors with sumptuous proclivities could further adorn themselves with gold lace, but if of frugal mind they were permitted to replace it with plain braid.

◆

P. M.—If the patient died after admission to the hospital the coroner can order a post-mortem examination to be made without any fee. Whether the house surgeon is legally entitled to a fee for his attendance is doubtful, but he never receives such a fee.

H. J. H.—The address of the General Medical Council Offices is 299, Oxford-street, London, W. If our correspondent will communicate with the registrar he will be informed as to what steps should be taken. There is a small fee.

Cymro will find at page 647 of the last Students' Number of THE LANCET, published on Sept. 1st, 1900, a full answer to his question.

ERRATUM.—In the report of the meeting of the Clinical Society held on April 26th (THE LANCET, May 4th, p. 1276) the observations on Dr. Lee Dickinson's case attributed to Dr. A. G. Phear were not made by that gentleman. The observations on Dr. Percy Kidd's case attributed to Dr. W. Forbes Ross were made by Dr. A. G. Phear.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. D. B. Lees: Demonstration of Selected Cases.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. *It is urgently necessary that attention be given to this notice.*

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to *the Agent to whom the subscription is paid, and not to* THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD. THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

The Erasmus Wilson Lectures

ON

THE PATHOLOGY AND DISEASES OF THE THYROID GLAND.

Delivered at the Royal College of Surgeons of England on Feb. 18th, 20th, and 22nd, 1901,

BY WALTER EDMUNDS, F.R.C.S. ENG.,

SURGEON TO THE TOTTENHAM HOSPITAL; SURGEON TO OUT-PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

LECTURE II.[1]

Delivered on Feb 20th.

MR. PRESIDENT AND GENTLEMEN,—Having in the previous lecture considered the effects produced by total excision of both the thyroid gland proper and the parathyroid glands, and also by the removal of the thyroid gland only, we have now to determine the results of removing the parathyroid glands only.

It 1896 it was pointed out by Vassale and Generali that if in dogs all the parathyroid glands were removed and the thyroid gland proper left the dogs would die just as they do, and with the same symptoms, as when the thyroid gland and the parathyroid gland are completely removed Their experiments have now been repeated several times and in the main they have been confirmed. My own results were as follows In 16 dogs it was intended to remove all four parathyroid glands, leaving the thyroid lobes intact; but it is not easy to find all the parathyroid glands in an operation, and it was subsequently seen that in seven of the dogs one (and in one case two) of the parathyroid glands had been left; in only nine then had all the parathyroid glands been removed, and it cannot be absolutely affirmed that in these no parathyroid had been left, because the only way of making sure is to cut and to examine consecutive sections of both thyroid lobes, and this was not done. However, in the nine dogs no parathyroid glands were subsequently found and it is probable that none were left. Of the nine dogs four died; one in two days, one in four days, one in seven days, and one in 28 days. The other five survived, but three of them had temporary symptoms; thus, of the nine dogs which underwent complete parathyroidectomy four died, three recovered after symptoms, and two escaped all ill consequences. In my hands, therefore, the results of parathyroidectomy were not so bad as were those of total excision, but, on the other hand, in a recent paper Vassale and Generali state that they have found them even worse—that is to say, that while both operations are fatal the dogs die more quickly after removal of the parathyroid glands only than after total excision, and further, that if after parathyroidectomy the thyroid lobes are removed a day or two later the dogs will live longer than they would have done had the lobes been left.

The changes which occur in the thyroid lobes which are left in these operations are very interesting—the colloid diminishes or completely disappears, and its place is taken by a watery secretion; the vesicles instead of remaining round become branched and the secreting cells become columnar or multiplying fill the cavity of the vesicles with round cells. These changes are identical with those described as "compensatory hypertrophy," but the thyroid lobes do not appear to enlarge, but on the contrary sometimes they seem to become smaller; this, if confirmed, will coincide with the view that the parathyroid glands manufacture the secretion and the thyroid glands store it; when the parathyroid glands had been removed there would be no secretion for the thyroid lobes to store. The five dogs which, as just stated, survived excision of the parathyroids were subjected to the further operation of removal of one of the remaining thyroid lobes; two died after this and three survived; in these three the remaining thyroid lobe was excised; one died, and two, after temporary symptoms, recovered; these two lived therefore without either thyroid gland or parathyroid gland—in a state of complete athyroidea, in fact. The symptoms, and in the fatal cases the cause of death, were the usual symptoms of athyroidea—namely, tremors, unstable gait passing into paralysis of the hind limbs, emaciation, and great weakness; in two of the dogs marked narrowing of the palpebral fissures was noted. The thyroid lobes obtained by these later operations were sometimes normal and sometimes altered as described. In seven of the dogs some of the parathyroid glands had been removed, but it was subsequently found that in them one (and in one case two) of the parathyroid glands had been left. Only one of these dogs died, and that only after 72 days; thus in nine dogs with complete parathyroidectomy four died in 28 days; in seven dogs with incomplete parathyroidectomy only one died, and that only after 72 days; it died with paralytic symptoms. Although the other six dogs did not die, four of them had symptoms from which they recovered; these six dogs were submitted to further operations; in one both thyroid lobes were removed simultaneously; it died in consequence; in the other five one thyroid lobe was removed; three died in consequence; two survived, but one of them had symptoms; from each of these two survivors the remaining lobe was removed; they both died in consequence. Changes were noticed in the eyes of some of these dogs; in two of the dogs after an incomplete excision of the parathyroid glands widening of the eyes was seen and after a later operation the eyes became retracted and the palpebral fissures narrowed. In one dog two parathyroid glands were removed and two were left, one on each side; this operation produced no change in the eyes; the removal of one parathyroid gland with one lobe was followed by widening of the eyes, and the subsequent removal of the other lobe, also with a parathyroid gland, was followed by narrowing of the eyes and death from athyroidea It would seem that removal of the parathyroid glands, if not fatal, causes (if any change) exophthalmos, but in fatal cases, whether produced by removal of the parathyroid glands or by total thyroidectomy, the eyes often become very narrow.

We have now completed our survey of the effects of the three main excision operations, but on account of the importance of exophthalmos in Graves's disease it will be well to review the effects of these operations on the eyes.

To commence with dogs The effects on the eyes of dogs of complete excision of both the thyroid gland and the parathyroid glands is to make the eyes narrow; the dogs die from the operation and with narrow eyes. The next operation is removal of one lobe of the thyroid gland together with its two parathyroid glands, leaving the opposite lobe with its two parathyroid glands; this produces no effect on the health of the dogs, nor, as far as I have noticed, on their eyes. The same result, as a rule, follows removal of the thyroid gland proper, leaving one or more parathyroid glands. Occasionally after leaving only one parathyroid gland symptoms come on and then the eyes may become narrow. Removal of parathyroid glands, leaving one parathyroid gland and the whole or part of the thyroid gland proper, may be followed by the eyes becoming wide, and after a further operation they may become narrow. Finally, total excision of all of the parathyroid glands often causes death, and in one case at least there was narrowing of the eyes.

In rabbits two of the parathyroid glands lie distinct from the thyroid gland as a rule, and it is a simple operation to remove these and to leave the thyroid gland proper with presumably two parathyroids, or to perform the reverse operation. I made a series of experiments to test the effects of these operations on the eyes. Of six rabbits in which the thyroid gland was removed three have since died, and they died with narrow eyes; in one of the survivors the eyes are now normal, having once been narrower than before operation; in one they are now normal, having once been wider; and in the third they are becoming normal, having been wider. On the other hand, a much stronger tendency to the eyes becoming wide was seen in the rabbits from which two parathyroid glands were removed; out of five experiments in one no change occurred, but in all the other four the eyes became wide for a time, but have since become normal.

In monkeys the only operation performed was total excision of the thyroid gland and the parathyroid glands; as a rule (and always at the latter stage of the illness when the monkey is dying from athyroidea) the eyes are narrower; but occasionally after the operation the eyes become wider.

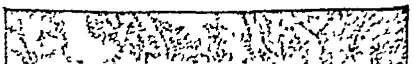
The conclusion of the matter would seem to be that excision of the thyroid gland and the parathyroid glands produces enophthalmos with narrowing of the palpebral fissures; total parathyroidectomy would seem to produce the same, and so also (if it produces symptoms) does excision of the thyroid gland proper, but certain operations not fatal at the time, and especially those in which the parathyroids are interfered with, may be followed by exophthalmos with widening of the palpebral fissures. The same operation may be followed by first widening and later narrowing, but I have never seen the reverse—at least, not as a permanency. It will be noticed that these eye changes tend to support the suspicion that the parathyroid glands are involved in the pathology of Graves's disease.

---

[1] Lecture I. was published in THE LANCET of May 11th, 1901, p. 1317.

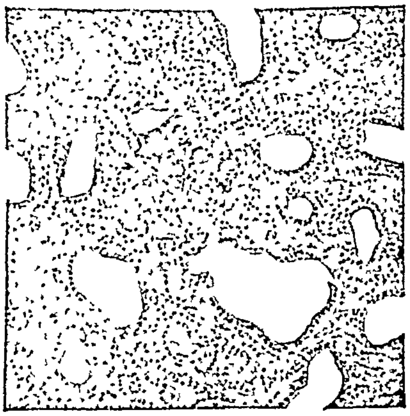
The preceding experiments apply to the action of the thyroid gland, or of portions of it, when the nervous supply is intact; but the well-known effect on the salivary glands of interference with their innervation leads to the question whether the internal secretion of the thyroid gland is under the control of the nervous system. Various experiments have been made to test this: Schiff stripped the sympathetic fibres accompanying the blood-vessels going to one lobe of the thyroid gland from them, leaving the opposite lobe intact; on subsequently comparing the lobes of the two sides he could find no difference between them; the interference with the sympathetic had produced no result. Horsley tried the effect of dividing the recurrent laryngeal nerve to one lobe; that, too, produced no difference on the two sides. I myself divided the vagus on one side; as the division was below the origin of the superior laryngeal nerve the operation was practically the same as Horsley's division of the recurrent laryngeal nerve and the result was the same—a negative one. Katzenstein tried the effect of electrically stimulating one lobe of the thyroid gland; that, too, produced no alteration in the microscopical appearances of the two sides. However, at last a positive result was obtained. Exner found in two experiments on cats that the division of the superior and inferior laryngeal nerves supplying one lobe of the thyroid gland and the excision of the opposite lobe caused severe tetany, showing that the function of the "paralysed" lobe was greatly interfered with. I have repeated Exner's experiment (with an unimportant modification) and have obtained similar results. The experiments were made on dogs and consisted in excising a length of the superior laryngeal nerve on one side and also on that side a length of the vago-sympathetic at the level of the thyroid, and finally on the opposite side excising the thyroid lobe together with its parathyroid gland. The experiment was performed nine times; the result was that three of the dogs died, one in 18 hours, one in two days, and one in three days. Of the six survivors four had athyroidic symptoms and two had no symptoms; thus out of nine dogs operated on seven had symptoms and three of them died; it is therefore to be inferred that the secretion of the thyroid gland is under the control of the central nervous system; that this is so is further supported by the microscopical examination of the thyroid lobes which had had their innervation interfered with. Out of the nine experiments two dogs survived without symptoms; in one the first lobe removed did not appear normal under the microscope and it will therefore be safer to reject this experiment altogether; in one the operated lobe appeared normal; as this dog had no symptoms it is possible that there was something wrong in the experiment—any way, the absence of symptoms and of alteration in the lobe go well together. With respect to the remaining dogs which had symptoms, from two there are no specimens, from one because the dog is still alive; there remained then five specimens from five dogs, all of which had symptoms. The results of microscopical examination were: (1) from all five of these lobes the colloid had completely disappeared; and (2) in four of them the secreting cells had multiplied into the cavity of the vesicles; this is different from the usual appearances in compensating hypertrophy, in which, as a rule, the secreting cells become columnar but do not invade the cavity of the vesicle—it is rather the appearance seen in any remaining portion of a lobe when compensation has failed and death is occurring from athyroidea. (Fig. 7.) With respect to the fifth lobe, the dog having survived the experiment the lobe was excised 49 days later. It was greatly enlarged and weighed 3·5 grammes, which is three or four times the normal weight. All colloid had disappeared, but the secreting cells and their progeny were not in this case filling the cavities of the vesicles which contained instead a watery secretion. The great size of the lobe was due to the growth of young thyroid tissue between the vesicles. (Fig. 8.) It is clear then that the interference with the nerve-supply produces very serious symptoms, and when we come to consider the pathology of thyroid disease we must be prepared to admit the possibility of defective innervation being the cause of serious symptoms and pathological changes. With respect to the sympathetic nerve-supply, Schiff, as stated, came to the conclusion that it produced no effect. In the submaxillary gland the sympathetic carries but few secreting fibres, the main supply being through the chorda tympani. Such, then, are the results of deprivation of thyroid secretion by operations for the removal of the thyroid system in whole or in part, or by interference with its nerve-supply.

FIG. 7.



From a dog the parathyroid glands were removed; the dog died in seven days in consequence. The drawing shows the changes which occurred in the thyroid lobes (which were left).

FIG. 8.



A microscopical section of the thyroid lobe of the dog referred to in the text.

We now proceed to consider the results arising from an excess of thyroid gland in the system. This can theoretically be effected in two ways—either by grafting additional thyroid gland into the body or by the administration of thyroid gland for thyroid preparations. Grafting, as already stated, seems unsatisfactory, and it has not yet been carried out so as to justify any physiological conclusions as to its effects; on the other hand, the results of thyroid-gland feeding have been carefully investigated both in normal and in diseased subjects. In a healthy man Dr. G. F. Johnston found by experiments on himself that after taking from four to nine thyroid-gland tablets a day there was acceleration of the pulse from 70 to 120, accompanied by palpitation, flushing, tremors, sensation of heat, and perspirations. Similarly, M. Gagnevin, a medical student, took for eight days full doses of raw thyroid gland; this produced palpitation, a rapid pulse, tremors, perspiration, flushings. and (as was noticed by his friends) exophthalmos. Also Dr. Béclère has recorded a case of myxœdema in which very large doses of thyroid-gland preparation were taken. The disease was relieved, but temporary symptoms of thyroid intoxication were produced; they were quickened pulse, quickened respiration, rise of temperature, sensations of heat, increased perspiration, mental agitation, tremors, incomplete paraplegia, increased secretion of urine, temporary albuminaria, and a certain degree of exophthalmos. Similarly, Easterbrook found in the human subject that the administration of thyroid gland produced: (1) a loss of weight, about seven pounds a week; (2) some pyrexia; (3) some increase of perspiration; (4) diminution of red blood corpuscles; (5) headache; (6) tremors; (7) an increase of pulse-rate by about 40 a minute; (8) an increase of rate of respiration by about six a minute; (9) a diminution of appetite; (10) an increase of menstruation; and (11) an increased amount of urine, often of albumin, but never of sugar. He concludes that thyroid substance is a profound katabolic stimulant.

In healthy animals thyroid-gland administration does not produce much effect unless carried out in very large doses. I gave a dog two thyroid glands of the sheep a day without any obvious effect, also to another dog the thyroid glands of 16 sheep without any result, and others have made the same experiment also with negative results. Chasevant fed a dog with the thyroid gland of the ox. He gave to the dog in 57 days 1361 grammes of thyroid gland; the only result was loss of flesh—the weight fell from six and a half to eight kilogrammes; there were no other symptoms, no rise of temperature, no loss of good temper, and no morbid symptoms whatever. In 1895 Ballet and Enriquet experimented on dogs in three ways: by thyroid-gland grafts in two cases, by thyroid-gland feeding in six cases, and by thyroid-gland injections in 12 cases; in three out of the six dogs fed with thyroid gland distinctive symptoms were obtained; these consisted in rise of temperature, rapid pulse, tremors, conjunctivitis, emaciation, and in one animal quite distinct exophthalmos. In two of the animals in which the injections were used there was observed to be a slight prominence of the eyes not amounting to exophthalmos

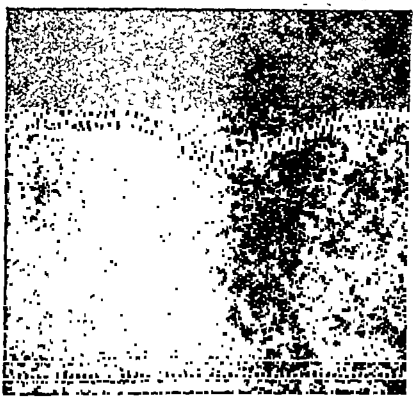
In a rabbit to which Cunningham administered by the mouth 0·1 gramme of thyroid extract exophthalmos was caused. He gives a photograph of the rabbit which shows the exophthalmos very clearly.

In monkeys I have found the administration of large doses of thyroid extract produce marked results. The preparation chiefly used was thyro-colloid which is made from the thyroid glands of sheep by a process devised by Dr. R. Hutchison. In principle it consists in dissolving out the colloid with a dilute alkaline solution and precipitating with acetic acid. Large doses of this preparation were administered to six monkeys, the daily dose corresponding to from one-half to three whole thyroid glands of a sheep a day. Well-marked symptoms were produced—namely, proptosis, dilatation of pupils, widening of palpebral fissures, erection of hairs on the head, the hair falling out in patches, paralysis of one or more limbs, emaciation and muscular weakness, and finally death from asthenia. The average life of the monkeys after the commencement of this treatment was 76 days.

Of the above effects those produced on the eyes are no doubt caused mainly by action through the cervical sympathetic. Division of the cervical sympathetic causes (1) recession of the eyeball, (2) contraction of the pupil, (3) narrowing of the palpebral fissure, (4) œdema and flushing of the skin round the eye, (5) swelling of the caruncle, (6) projection of the pinna from the side of the head, (7) puckering of the skin of the muzzle, and (8) flattening of certain hairs on the forehead which cannot then be elevated by emotions which affect the corresponding hairs on the opposite side. On the other hand, stimulation of the cervical sympathetic produces: (1) proptosis of the eyeball; (2) well-marked dilatation of the pupil; (3) widening of the palpebral fissure; (4) lying back of the pinna; and (5) erection of certain hairs on the head.

In order to test how far the effects upon the eye of thyroid-gland feeding were produced through the sympathetic in two monkeys I excised a length of the cervical sympathetic on one side. After allowing a few days for recovery from the effects of the operation thyroid-gland feeding in large doses was commenced; 12 days later it was found on comparing the monkeys with sketches made before operation that on the unoperated side the palpebral fissure had become very wide, the eyeball very prominent, and the pupil much dilated. On the side on which the sympathetic had been divided the fissure was narrow, the eyeball not prominent, and the pupil not dilated. In one of the monkeys 12 days later the difference in the eyes was much less marked, although the feeding had been continued; this may possibly be due to some repair having occurred in the sympathetic. This is said to happen even when, as in this case, a length of the nerve has been excised.

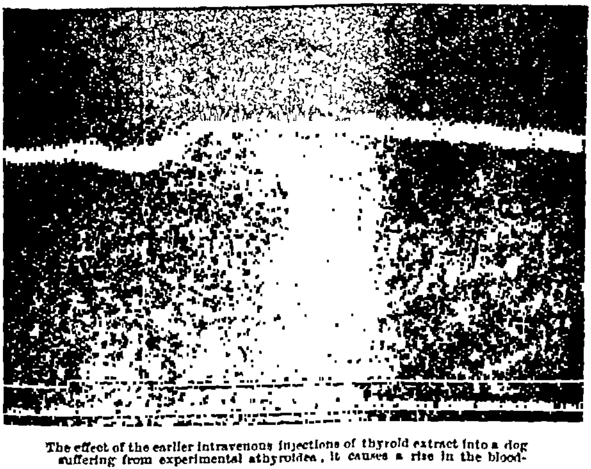
FIG. 9.



The effect of intravenous injection of thyroid extract into the normal dog. The injection was made during the time shown upon the upper line; it caused a fall in blood-pressure. (Read the tracings from left to right.)

There are comparatively few observations on the action of parathyroid gland. Easterbrook in his investigation found that it produced no affects, thus markedly contrasting with the thyroid gland. Hutchison tried parathyroid gland in a case of myxœdema, but without producing any improvement; but Hutchison states that parathyroid gland undoubtedly produces beneficial results in animals that have been deprived of their parathyroid glands.

FIG. 10.

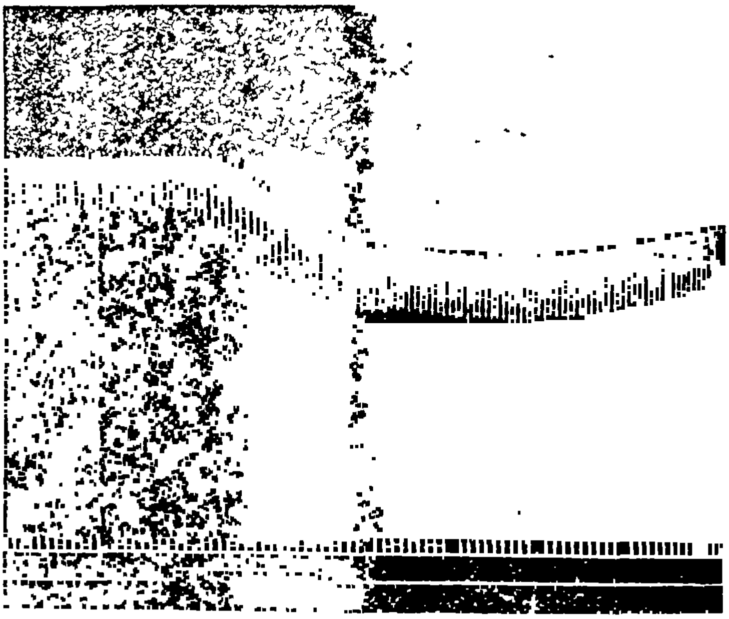


The effect of the earlier intravenous injections of thyroid extract into a dog suffering from experimental athyroidea, it causes a rise in the blood-pressure.

The effect of the intravenous injection of thyroid extract into animals has been investigated by Oliver and Schäfer; they found a marked fall in the blood-pressure produced, but the force of the heart's contraction and the pulse-rate were not materially altered.

The effects of the injection of thyroid extracts into thyroidless animals have been tried by von Cyon who has written a series of very interesting papers on the relations of the thyroid gland and the heart, and (with the kind assistance of Dr. T. G. Brodie) by myself. The injection of thyro-colloid into thyroidless dogs causes a rise of blood-pressure—at least, that is the effect of the earlier injections; later injections produce, as in the normal, a fall; these phenomena may be explained by assuming that thyro-colloid stimulates both the depressor and accelerator mechanisms, that while the former preponderate in the normal, athyroidea so alters their relative response that in it the accelerators preponderate at first, but that the earlier injections of thyro-colloid so revives the depressors and vagi that the later injections produce the normal effect. Von Cyon states that in the goitrous animals of Berne and in athyroidea the excitability of the vagi and depressors is diminished or abolished and that of the sympathetics (vaso-constrictor and accelerator) is increased. (Fig. 9, Fig. 10, and Fig. 11.)

FIG. 11.



The effect of the later injections of thyroid extract into a thyroidless dog; it causes, as in the normal, a fall of blood-pressure.

A Clinical Lecture

ON

CASES ILLUSTRATING THE SURGERY OF THE THYROID GLAND.

Delivered at St. Thomas's Hospital on Oct. 17th, 1900,

BY HENRY BETHAM ROBINSON, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON, SURGEON IN CHARGE OF THE THROAT DEPARTMENT, AND LECTURER ON ANATOMY, AT ST. THOMAS'S HOSPITAL; SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

[THE lecturer first reviewed certain points in the anatomy and physiology of the gland, referring particularly to the development of the pyramidal lobe and to the effects produced by the absorption of the thyroid secretion. He then said:]

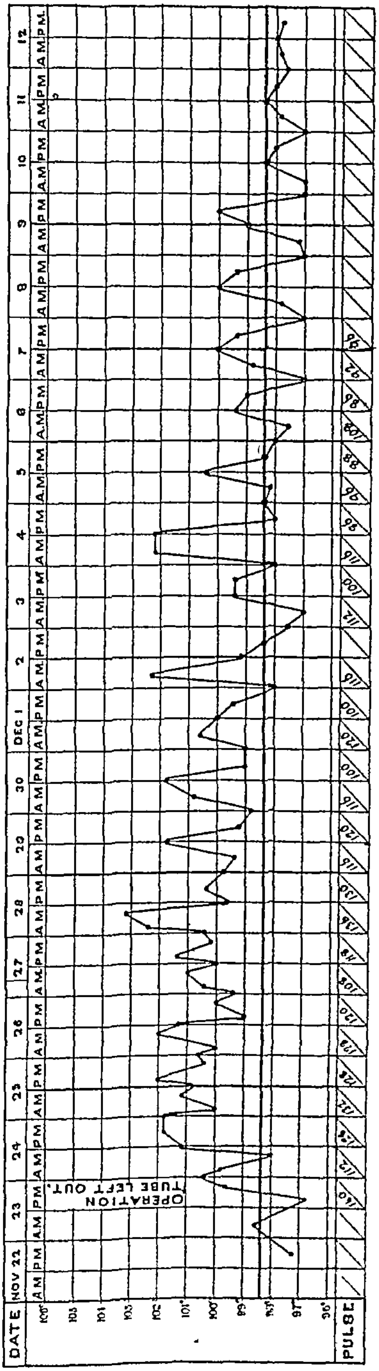
The first group which I will discuss consists of cases of parenchymatous goitres where there was general enlargement of the gland, almost symmetrical, without any pulsation or other signs of Graves's disease. Their consistency is generally soft, but the density of the inclosing fascia often produces a certain amount of firmness. The enlargements may take place slowly, but in some cases they may develop rapidly, producing a characteristic and distressing train of symptoms. This rapid increase seems to occur particularly in young subjects about the onset of puberty and no doubt it bears some direct relation to the awakening activity of the sexual organs.

CASE 1. *Parenchymatous goitre; reduction under thyroid extract.*—The patient, a male, aged 17 years, was admitted to hospital on July 31st, 1896. One of his sisters had had a unilateral swelling for 12 years. 12 months previously he had had influenza and just afterwards his neck was noticed to be enlarging on both sides. The swelling increased gradually with at times, he thought, a slight decrease. There was no pain but it seemed to throb. His breathing was noisy when at work and sometimes he had a feeling of suffocation. About four months before he had had a bad attack of dyspnœa at night but this had never been repeated: he slept well usually. There was discomfort on swallowing. Both lobes and the isthmus formed a soft, symmetrical enlargement without any pulsation. His eyes seemed a little prominent, but this appeared to be only accidental, as there were no other signs suggesting Graves's disease. His neck, measured through the isthmus, was 15¼ inches on August 3rd and thyroid extract was ordered, as he had no urgent symptoms. This produced remarkable benefit, as on the 6th the measurement was 14¾ inches on the 10th 14½ inches, on the 14th 14¼ inches, and on the 18th 14 inches. Accordingly he was discharged to go on with the treatment outside.

CASE 2. *Parenchymatous goitre; enlarged pyramidal lobe; operation; thyroidism; recovery.*—A youth, aged 16 years, a patient of Dr. G. H. Wickham of Fleet, Hampshire, came under my care on June 8th, 1897. Between four and five months the swelling of the neck had been noticed. It had grown gradually at first, but during the last six weeks its growth had been rapid, so that marked dyspnœa and some difficulty in expectorating had resulted. He was rather a heavy-looking boy who when sitting up did not appear to have any difficulty in breathing except on much talking, but in the reclining position his respiration was noisy with marked stridor. He was very restless at night and he constantly started up with a feeling of suffocation. The gland was considerably enlarged, the lateral lobes symmetrically; between these was a central mass inclining rather to the left of the mid-line, reaching almost to the hyoid bone. The whole gland was somewhat elastic, uniform in consistency, and without any prominent or fluctuating areas. There appeared to be no extension behind the sternum, but there was undoubted tracheal stridor. During the day and night of the 9th the patient's breathing was much embarrassed, and in the early morning of the 10th his condition seemed to be so grave that it was determined to relieve the pressure on the trachea. A vertical incision was made down to the gland and the isthmus with an enlarged pyramidal lobe was found completely to cover the trachea. He now became asphyxiated, and as an immediate opening into the trachea was imperative, the gland was cut through (its thickness being quite three-quarters of an inch) down to the trachea, which was opened and a No. 12 catheter was introduced. With ether and strychnine he soon revived. The operation was then proceeded with. The isthmus was removed without much hæmorrhage and without being ligatured laterally. The trachea was found to be much compressed laterally and softened from absorption of the cartilaginous rings. The wound was then left open at the bottom and was lightly packed with gauze, and an ordinary tracheotomy tube was left in. The next day, as his breathing was not very satisfactory, a König's vertebrated tube was inserted with much subsequent benefit, and it was finally removed on the eighteenth day. For a fortnight after the operation the patient had a very erratic temperature without any local cause which, associated with some feeling of oppression, slow healing of the wound, and somewhat marked watery discharge, pointed to thyroidism from the absorbed secretion. Locally the lateral lobes dwindled rapidly after the operation and they became much softer. He left the hospital at the end of the month. His subsequent progress has been most satisfactory; he has never had any more enlargement and he can work hard without dyspnœa (October, 1900)

CASE 3. *Large parenchymatous goitre with pyramidal lobe; section of the isthmus and removal of the lobe; thyroidism; recovery.*—The patient, a female, aged 15 years, came under my care in St. Thomas's Hospital on Nov. 22nd, 1899 Beyond that of the grandmother having a goitre there was no other history. The girl had always been healthy until three years before, when a lump in the front of the neck was first noticed; it was small and was confined to the middle line During the fortnight before admission the swelling had been getting rapidly larger, especially at the sides of the neck. When lying still there was no dyspnœa, but on any exertion it was very marked and she felt nearly suffocated; in fact, she was hurried to the hospital after a very severe attack in which it was thought she would succumb. On admission the thyroid gland was found to be enormously enlarged and towards the lower part could be felt a cleft in the middle line between the lateral lobes corresponding to the isthmus. Between what were made out to be lateral lobes above was a central swelling, a little more to the left side, which reached up to the hyoid bone On relaxing the neck the whole mass was rather soft, without any pulsation There was some tracheal stridor and any lateral movement of the head brought on a severe attack of dyspnœa There was no exophthalmos, but the pulse was rather irregular and about 100. As the patient's condition did not permit of delay to try the administration of drugs, she was brought to the theatre on the afternoon of the 23rd Chloroform was administered and a vertical incision was made in the middle line through the skin and fascia, several very engorged veins having to be tied, and the growth was exposed. At this stage she became cyanosed and stopped breathing. As artificial respiration did not relieve this condition an opening was made into the trachea by cutting down through the right side of the central mass—this opening was through the crico tracheal interval and the first ring—and a tube was introduced. The patient's breathing then went on satisfactorily and the operation was proceeded with. The isthmus which consisted of a fair thickness of thyroid tissue was cut through down to the trachea and portions of it were removed but not ligatured off The pyramidal mass connected with the isthmus above was able to be dissected away and was removed *in toto* After all bleeding, which was not severe, had been stopped the upper part of the wound was stitched up with horsehair, but the lower part was left open and was loosely packed with cyanide gauze. The trachea was found to be much flattened laterally. As before leaving the table the short tracheotomy tube did not seem satisfactory it was taken out and a König's tube was put in its place. After reaching the ward the patient again became cyanosed and began to struggle violently; a quarter of a grain of morphia administered hypodermically brought relief. At about 11 P.M. she again had dyspnœa and the tube was removed. As her breathing seemed to be much easier without it it was kept out and the wound was covered up with sterilised gauze As shown in the annexed chart there was marked rise of temperature with rapid pulse lasting for nearly a fortnight. This was accompanied by restlessness, at times a feeling of suffocation and some cough, but without any physical signs in the chest. For some days there was watery discharge from the wound which was never offensive On Dec 2nd the tracheal wound was closed and the remainder granulated up slowly. From this time onwards she had no drawbacks, but the wound was not healed until Jan. 10th, 1900 There was no discomfort on moving the head. The lateral lobes diminished in size very rapidly after the operation. The growth on examination proved to be a soft parenchymatous goitre

The last two cases just detailed have several important features in common which are worthy of note There had been in adolescence the somewhat rapid enlargement of the gland, attended with breathlessness, particularly on exertion. In both the isthmus of the gland was very well developed, rendering the position of the trachea deeply placed, and this was associated with the presence of the pyramidal lobe



Temperature and pulse record of Case 3.

The probable thickness of the gland over the trachea should always be anticipated and, knowing how liable such patients are to failure of breathing during the operation, the surgeon should never embark on such a procedure without having at hand a long catheter and a König's flexible tube. The tissue forming the isthmus was freely divided in both cases and in the girl's case the pyramidal lobe was removed in addition. Before section the isthmus was not ligatured laterally. The trachea on exposure was in each case compressed at the sides and its walls were thinned; in spite of this there were no unpleasant sensations afterwards on free movement of the neck. The after-results of the operation were eminently satisfactory from the marked relief of pressure and from the dwindling of the enlarged lateral lobes, but as the immediate sequel certain well-defined symptoms were present. There was an extremely irregular high temperature for some days afterwards, with a feeling of suffocation and restlessness, and a rapid irregular pulse, but without any physical signs. This combination of symptoms has been recorded before in cases described by Mr. Victor Horsley and Dr. A. J. Rodocanachi and by Mr. F. T. Paul of Liverpool. They are, in fact, due to the absorption of the secretion from the cut thyroid gland by its vessels and lymphatics and the symptoms resulting are such as would occur from an overdose of the thyroid extract. In some cases death has followed without any lesion being found at the necropsy, and I can picture such a case some years ago in which, before the correct explanation was forthcoming, death was attributed to iodoform poisoning. To prevent such absorption the risk of tension should not be run from suturing up too much. It is better to leave the bottom of the wound open and to pack lightly with gauze, removing the same from time to time when soaked with the wound exudation. If symptoms should so indicate the wound in addition may be irrigated. It should also be noted that although the wound may be quite clean healing is very slow. On the occurrence of restlessness, breathlessness, &c., good effects have been obtained by the administration of morphine, and arsenic may be tried which has been found of use when an overdose of the extract has been administered by the mouth.

The second group of cases which I will refer to are the thyroid gland adenomata, encapsuled tumours embedded in the gland substance as elsewhere. Usually they occur singly, but sometimes they may be multiple in a lateral lobe; more rarely both lobes may contain these encapsuled masses, and then some care must be taken in establishing the diagnosis between such an occurrence and a general enlargement of the gland itself. Upon the following points we may rely: the improbability of symmetry and, if there is marked difference in size, the possibility of diversion of the trachea from its normal line—instead of the outline of the gland being preserved, only on a larger scale, there are irregularity of the surface and some convex prominence usually forwards. This irregularity may, however, be somewhat masked if there is an associated enlargement of the parenchyma, but the latter complication may be reduced and the diagnosis strengthened by the administration for a time of thyroid extract. A unilateral enlargement is almost without exception due to an adenoma, especially if malignant disease can be excluded. There is usually a localised convexity in some part of the anterior surface of the gland, and if the enlargement is marked the trachea will be displaced to the opposite side. The development of these tumours is, as a rule, slow, so that they are well borne; pressure may, however, occur on the surrounding structures and corresponding symptoms may be produced.

CASE 4. *Cystic adenoma of the right lobe; removal.*—The patient, a female, aged 38 years, was admitted into St. Thomas's Hospital on August 6th, 1896. She first noticed the lump on the right side of the neck four months before when it was of the size of a small egg, but since that time it had reached the size and shape of an orange. No inconvenience was produced. The tumour over its greatest prominence was somewhat elastic. An incision was made down to the gland along the inner border of the sterno-mastoid. After incising the thin capsule of gland tissue the greyish wall of a cystic tumour was exposed and, after evacuating some greenish-brown fluid, its walls were easily dissected out from the surrounding gland substance which was left, especially at the upper part. The gland substance then came together easily and the wound was sutured up, a small gauze drain being left at the bottom of the wound which was removed at the end of 36 hours. The patient made an uneventful recovery. The adenoma had a well-marked fibrous capsule with one main cyst anteriorly into which projected soft glandular processes and on the deep aspect especially of this cyst was somewhat soft and rather grey glandular tissue in which were other small cysts.

CASE 5. *Adenoma of the right lobe; enucleation.*—The patient was a female, aged 17 years, who was admitted into the hospital in June, 1899. In the right lobe was a small convex nodule of about the size of a walnut, prominent just in front of the sterno-mastoid and about the middle of the gland which had been noticed for one year At the operation, after incising through some normal thyroid tissue a greyish-white tumour was exposed which was easily enucleated from the lower and inner side of the lobe. On section the adenoma was almost circular and about one and one-eighth inches in diameter. Inside the thickened fibrous capsule was a soft, yellowish, translucent, gelatinous tissue, without any cysts, but with a few small blood coagula flecked through it.

CASE 6. *Cystic adenoma of the right lobe; enucleation.*—The patient, a female, aged 34 years, was admitted into the hospital in June, 1899. In the right lobe was a fairly large convex swelling reaching from the middle line to under the sterno-mastoid. On making the incision in the usual way the gland was exposed with large veins coursing over its surface. Cutting through normal-looking thyroid tissue a greyish-brown convex surface was exposed, which was the tumour, and this was easily enucleated from the outer and lower part of the gland. The tumour was of the size of a hen's egg, consisting of one fair-sized cyst which contained a dirty-brown fluid and soft, greyish, friable tissue round it.

CASE 7. *Large solid adenoma of the left lobe; great displacement of the trachea; enucleation.*—The patient, a male, aged 51 years, was admitted into the hospital under my care on April 24th, 1900. His father had died from cancer and his mother from some lung complaint. She, however, had an enlarged thyroid gland, as had also one of his sisters (who was operated upon and who died soon after) and one brother. At the age of 20 years the enlargement on the left side of the neck was first noticed, which slowly and steadily increased until about a year before admission; since then it had remained stationary. For the past 10 years there had been dyspnœa; this he attributed partially to an injury to his ribs in 1888. He first came to me at the beginning of 1897 with lead-palsy which soon improved. As his health, owing to cardiac disease, was not satisfactory enough to allow of removal of the growth, my colleague, Dr. H. W. G. Mackenzie, had him under his care for a while. During this period the patient had had thyroid extract, this accounting probably for any further increase being checked and certainly rendering the adenoma more defined. On examination there was a hard tumour in the left lateral lobe, markedly convex forwards and upwards; its surface seemed to be fairly smooth. There was no translucency and no fluctuation or pulsation. The trachea was pushed well over to the right side of the mid-line. The larynx was normal. The heart was enlarged and there was a systolic bruit originating at the mitral valve; its condition had so improved that my colleague agreed that operation might now be performed without any great risk. Therefore on May 17th an incision about five inches long was made along the anterior border of the sterno-mastoid, with a second one two inches long at right angles to the first. On exposing the thyroid gland numerous large veins coursed beneath its capsule which were taken up, divided, and tied. The gland was incised to a depth of a quarter of an inch when the tumour was exposed and enucleated from its capsule of gland tissue. The rings of the trachea on their left side were decidedly thinned. The thyroid tissue was brought together by buried fine silkworm-gut stitches and a gauze drain (which was removed in 36 hours) was left in the bottom of the wound. The tumour was almost globular, with a diameter of five inches. Its structure was very solid and firm, containing small cysts, none of which exceeded in size a small nut; in its centre were marked white fibrous patches and over the periphery calcification was seen in plates. With reference to his after-symptoms there is not anything special to report. The pulse remained steady between 70 and 80 and there were no symptoms suggesting thyroidism excepting some irregular temperature for the first week (this, however, never exceeded 101° F. except on the night of operation) without any trace of wound infection. The patient left the hospital with his wound healed on June 6th, and since that time he has wonderfully improved in health.

CASE 8. *Multiple adenomata of the left lateral lobe; marked dysphagia from pressure; enucleation of three separate tumours.*—A man, aged 48 years, was sent to me on August 23rd, 1900, by Mr. E. C. Walter of Wallingford complaining of discomfort and difficulty on swallowing. He had an enlargement of the left lobe of the thyroid gland, which was irregular and firm; the gland moved freely up and down on swallowing. There was nothing abnormal in the larynx and œsophageal tubes could be passed without difficulty. He had not lost flesh. His dysphagia thus seemed to be related to the thyroid swelling. The account given of the latter was that it had only been noticed for two months. For the relief of the dysphagia and from the possibility of early malignant disease I advised exploration. The patient entered the hospital on Sept. 10th and the operation was performed on the 15th. A four-inch incision along the anterior border of the sterno-mastoid was made. On exposing the gland the anterior prominence was well marked and it felt elastic. The gland substance for one-eighth of an inch was incised when the grey-coloured adenoma was exposed and enucleated from the front and inner side of the gland. Inside its fibrous capsule was very soft cystic glandular tissue, with one very marked cyst, the anterior prominence, which contained a brown blood-stained fluid and papillary processes from its wall. To the outer side and behind this was felt another hard nodule which was enucleated. This was a more solid adenoma, with minute cysts, of about the size of a filbert. Another hard nodule could then be made out deeply placed towards the back of the lobe pressing backwards on the œsophagus. This was cut down upon and also enucleated and it proved to be almost solid and of the size of a hazel nut. The gland substance was then brought together with fine salmon gut and a small gauze drain was inserted into the bottom and brought out at the lower angle of the skin incision. This was removed after 36 hours and the wound was completely healed by the 22nd. After the operation the patient lost his feeling of dysphagia and he left the hospital quite cured. Although the adenoma had been removed from such a deep site there was no evidence of any interference with the recurrent laryngeal nerve.

In dealing with these adenomata strict conservatism should be adopted. It is quite unnecessary to remove the whole lateral lobe, for in most cases without much difficulty separation can be effected between the thinned-out gland tissue and the tumour. Further advantages of this are obvious. There is less disturbance of the surrounding tissues, so that the operation is not nearly so formidable and the risk of damage to the recurrent laryngeal nerve with the subsequent laryngeal paralysis are practically *nil*. The normal gland tissue left behind can still go on producing its internal secretion. The difference in colour between the reddish thyroid tissue and the greyish colour of the adenoma should be noted so as to define the plane of separation between the two.

Removal with the knife is by far the most satisfactory way of dealing with these adenomata, but less severe measures have been and are advocated. Tapping with or without the injection of iodine and drainage have been used. Simple tapping is merely temporising; it will have to be repeated and the risk of hæmorrhage into the cyst is run. Injecting iodine and drainage may be attended by suppuration, bad enough if limited to the cyst cavity, but in some cases it may burrow in the connective tissue of the neck.

The structure of these adenomata varies from a soft glandular tissue to a more solid fibrous type. In both cysts are met with, single or multiple, and in the former they may occur by the breaking down of the soft tissue and hæmorrhage; rapid enlargement with discomfort would point to the latter occurrence. The more chronic the tumour the greater is the likelihood of its connective tissue basis being dense and fibrous. Marked cicatricial patches may be found like scars through the growth, and in these calcification may occur which process may be also seen in plates on the periphery of the adenoma.

ISOLATION HOSPITAL ACCOMMODATION.—At the last meeting of the Bristol City Council it was reported that the Health Committee had instructed the city engineer to prepare plans for additional buildings at Ham Green to accommodate 63 patients. This will raise the total accommodation to 200 beds which will still be less than the minimum recommended by the Local Government Board. The cost of the extension is estimated at £24,660.

A PHARYNGEAL POUCH OF LARGE SIZE REMOVED BY OPERATION.[1]

BY RICKMAN J. GODLEE, M.S. LOND.,
HOLME PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, LONDON;
AND
T. R. H. BUCKNALL, M.S. LOND.,
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

THE patient whose case forms the subject of this paper came under Mr. Godlee's observation accidentally on May 18th, 1900. He had then a swelling which looked exactly like an enlarged gland on the left side of the neck at the level of the hyoid bone in front of the sterno-mastoid. It was, however, soft and on percussion gave a tympanitic percussion note and was clearly anchored to the top of the larynx, the movements of which it followed during deglutition. On squeezing it a squeaking sound was produced and a most uncomfortable sensation was experienced by the patient which shot up to the ear and which lasted for some days. The pressure caused an obvious diminution in the size of the tumour. It was clearly, therefore, a case of pharyngeal or possibly œsophageal pouch. He was seen once more during the next few days, and in view of the serious symptoms that usually, sooner or later, are said to supervene in these cases, he was urged to allow the pouch to be removed while it was still small, but he could not at this time make up his mind to accept this advice. He was not seen again until Dec. 31st, 1900, when he was admitted to University College Hospital, and the following history was elicited. The patient, who was 31 years old, had been in the habit of smoking to excess and had habitually taken more alcohol than was good for him. Twelve years previously he had received a blow from a fist on the left side of the neck which was painful, but which was followed by no special symptoms at the time. Two years later he began to feel something working up and down the left side of the neck on swallowing. It was not always present, but occurred from time to time, but no fresh symptoms occurred until about three years ago. During the last three years he had been liable to acute attacks, lasting usually about a fortnight, during which a lump developed at the left side of the neck and swallowing became difficult and painful, until at last he could only swallow liquids. At the end of the attacks the lump disappeared, sometimes gradually, sometimes suddenly during the night. He had had about seven such attacks and also slighter ones which he had cut short by squeezing the lump, which always caused the expectoration of a quantity of phlegm, and almost daily he had coughed up what he described as "a piece of flesh," about one inch long and curled up, which sometimes stuck in his throat and caused him to choke and vomit. A full feeling in the neck warned him some 20 minutes before the commencement of an attack. The last attack began on Dec. 21st and resulted in a much larger and more painful swelling than had ever occurred before, and the skin for the first time became red over the swelling, though the redness was evidently not inflammatory. On admission the swelling reached the middle line in front and the posterior border of the sterno-mastoid behind, overlapping and pressing back this muscle. It reached upwards to a point just above and behind the angle of the jaw, and downwards to the clavicle, the upper border of which it just overlapped. He said that it had extended still further back a few days previously. It projected fully one and a half inches from the normal surface of the neck. The tumour was very painful and tender, the skin was moveable over it, and it was freely moveable over deeper parts, except near the upper part of the larynx, to which it was fixed, and at which part it appeared to be thickened, though the rest of the swelling was evidently a very thin-walled cyst. The carotid vessels passed behind it. The percussion note all over it was tympanitic. When he held his breath and blew he could slightly inflate the tumour, which procedure produced a slight change in the percussion note. There was no enlargement of the cervical glands and no sign of pressure on nerves, though the voice was harsh and metallic. A laryngeal examination showed the parts to be normal and that the cords moved freely. The temperature was normal.

---

[1] The clinical part of this case is described by Mr. Godlee, the pathological for the most part by Mr. Bucknall. Read at the Royal Medical and Chirurgical Society on May 14th.

Operation.—The pouch was removed on Jan. 2nd, 1901, by a long incision over the most prominent part of the tumour. It was a delicate matter to dissect the thin skin from the surface of it, and whilst doing so the lump collapsed. It was not apparent that the wall had been pricked, but it is possible that this may have been the case. The anterior border of the sterno-mastoid (with the spinal accessory nerve entering it) was drawn back and the thin lower part of the cyst was then opened in order to make it easier to dissect it from the subjacent structures. The dissection was less difficult when the thicker upper part of the pouch was reached, and this was found to consist of two portions communicating by a rather small opening. At last the narrow pedicle was reached which passed through the thyro-hyoid membrane, but very careful probing failed to discover the actual communication with the pharynx. The superior laryngeal nerve was not seen. The thyro-hyoid was stretched over this deeper part of the cyst which lay altogether in front of the large vessels The tubular pedicle was then secured by catgut stitches, a fresh portion of it being divided as each stitch was passed. Finally, the stump was invaginated by four stitches passed after the manner of Lembert's sutures, and the larger wound was closed except immediately over the site of the pedicle, where a small plug of gauze was placed in case the stitches should give way. The wound, however, healed perfectly, complete asepsis being maintained; the last part of the plug was removed on Jan. 12th, and healing was complete on Jan. 19th. The temperature remained normal throughout.

A careful examination of the pouch after removal was made by Mr. Bucknall. The wall of the smaller upper portion was three millimetres thick, that of the lower larger part varied from one to six millimetres. The structure of the wall was fibrous, without any muscular elements except where some fibres of the platysma were incorporated with the outer surface. The lining was throughout glistening. That of the larger sac fell into folds like those seen in an hypertrophied bladder, but that of the smaller part was almost smooth, though showing this tendency to rugosity to a less extent Microscopically the outer part of the wall was made up of dense fibrous tissue with few nuclei. Within this was a layer of more nuclear connective tissue with numerous dilated venules, and in part showing signs of recent inflammation. On this, and resting on a definite basement membrane, lay the remains of the lining epithelium, which had in most parts desquamated and was only to be found intact in the deeper crypts. Where perfect this consisted of about from three to six layers of columnar cells with oval nuclei, the superficial layers being ciliated. The deeper layers, which alone remained over the greater part of the inner surface, were columnar or cubical; the superficial ones were long and regular, and ciliated with definite free borders united to form a plane inner surface to the sac, where they were not shed or concealed by débris. The inflammatory cells, which had in parts burst through the basement membrane, had evidently been the cause of the desquamation. Close beneath the epithelial lining lay several nodules of lymphoid tissue, and here also at one spot a group of acini were cut across, resembling in every detail of their structure a mucous salivary gland. The large cubical cells composing the lining of each acinus displayed various stages of secretive activity. A few ducts were also visible.

It is possible to obtain records of nearly 200 cases of pharyngeal pouch and fistula. They probably all arise in connexion with one or other of the visceral clefts, and the following varieties occur which depend upon the position of the obliteration of the cleft: (1) it may remain open throughout its entire length, giving rise to the complete fistula opening into the pharynx and on the side of the neck; (2) no external opening may be formed and a pharyngeal pouch with a blind extremity may remain; (3) the internal aperture may become shut off from the pharynx leaving a blind external fistula; and (4) both internal and external openings being closed a "dermoid" cyst of the neck may remain. In more than a third of all the cases the fistula was complete, and of the remainder the majority presented an external fistula, either blind or with the internal orifice so concealed that it could not be found. In several a pharyngeal pouch was observed to burst externally, giving rise to the formation of a complete fistula; and conversely the external orifice of a fistula has been known to close, giving rise to a pharyngeal pouch, or the internal orifice once patent has become occluded and a blind external fistula has remained.

These facts point among others to the unity of origin of the various conditions. The internal orifice, when present, has always been found in the pharynx, and not, as at one time was stated, in the larynx. This has been proved by dissection in three cases, by passing the probe in 12, by the laryngoscope in three, and by injection from below in 17 cases. It is usually small and, like the orifice of Stenson's duct, situated on a small papilla, but in one case it was large enough to receive the last joint of the finger. In those cases in which its anatomical position has been accurately defined it opened on the side wall of the pharynx close to the margin of the tonsil, and frequently in connexion with the fold of the palato-pharyngeus.

The external orifice, if it exists at birth, is situated at some point along the anterior border of the sterno mastoid; it is single and is sometimes guarded by a subcutaneous nodule of embryonic cartilage. The most common position is just above the sterno-clavicular articulation, but it may be found at some higher point along the anterior border of the sterno-mastoid, and it has been noted opposite the cricoid on a level with the top of the thyroid close to the great cornu of the hyoid bone and opposite the angle of the jaw. If it results from the bursting of a dermoid cyst or pharyngeal pouch, as a rule it is still generally situated at the edge of the sterno-mastoid, but the pouch may have reached some other position before it burst and several external fistulous apertures may in some cases be formed.

Where a complete fistula exists some varieties in its relation to surrounding parts have been noted, but in a general way it may be said to arise from the pharynx, near the great cornu of the hyoid bone, and to run down with the carotid vessels beneath the sterno-mastoid as far as the external orifice. Pharyngeal pouches and blind external fistulæ, as a rule, follow the same course.

The lumen of the canal is usually small and its course is tortuous, especially above, and the whole pouch or fistula may form little more than a fine cord-like band extending down the neck. But in those cases in which no external orifice exists, or in which such orifice becomes blocked or closed, there is a tendency for distension to occur, and a swelling is then formed in the side of the neck which may possess the typical features of a pharyngeal pouch—that is to say, it forms a thin-walled, resonant, globular tumour, moving with deglutition, perhaps becoming more tense on forcible expiration, and capable of reduction in size on pressure. It is very rare for food to pass into the cyst, as usually happens in cases of true œsophageal pouch; it is, however, common for mucus to be expectorated, as happened in the present case.

It is interesting to try to determine which of the visceral clefts is concerned in the development of such a pouch. But the problem is a difficult one, and the difficulty is increased by the uncertainty existing at the present time with regard to the structures that correspond to the particular clefts and arches; and it must be added that, as neither of us is a skilled embryologist, all information on these matters had to be taken at second hand.

It is generally held that in the first (or mandibular) arch the lower jaw is developed; in the second the styloid process, the stylo hyoid ligament, and the small cornu and part of the body of the hyoid bone; and in the third the great cornu of the hyoid bone. The relation of the larynx to the visceral arches has not been determined. As the neck of this pouch passed through the thyro-hyoid membrane it is clear that it could not have been connected with any cleft above the third. It remains to be seen whether, supposing it was connected with the third, it bears a right relation to vessels and nerves.

The relation of nerves to the upper clefts is held to be constant and is shortly as follows. The nerve that is associated with each cleft divides at the dorsal end and is distributed partly to the arch above (anterior) and partly to the arch below (posterior). Thus the seventh nerve is distributed partly to the first arch and partly to the second; the ninth (glosso-pharyngeal) partly to the second and partly to the third; and the tenth (vagus) partly to the third (external laryngeal) and partly to the fourth arch and to lower parts of the body. Unfortunately, the position of the external laryngeal was not ascertained at the time of the operation; the main trunk of the vagus was certainly behind the neck of the pouch. It is not possible, therefore, to say whether the external laryngeal was in front of the neck, as it ought to have been if the pouch were connected with the third or some lower cleft; it is, however, almost certain that it did occupy this position.

The relation of the carotid arteries to the clefts is not yet definitely settled, and the issue is confused by the fact that the embryo of the chick has been so much employed in the study of embryology and that the development of the carotids does not appear to be the same in birds as in mammalia. Another source of confusion arises from the fact that the vessels are displaced downwards (towards the thorax) in the course of development.

According to many good authorities, the external carotid is developed from the ventral aortic vessel and thus passes in front of the visceral arches, the internal carotid from the third arch and that part of the dorsal aortic vessel which is above (anterior to) it. If, then, this pouch were developed from the third cleft its neck ought to have passed behind the two carotids. But such was not the case. Both carotids were behind the neck and only one explanation suggests itself—that the pouch was quite small at the time when the vessels were being displaced downwards (towards the chest) and that in its subsequent growth it pushed up in front of the external carotid.

If we turn to the descriptions of other observers it is found that it is not infrequent for the neck of the pouch to pass between the external and internal carotids and that the relation of some of them to the second cleft appears to have been clearly made out. Thus König, Watson, Heuter, Rehn, Tricomi, and Gussenbauer all noted that the canal passed beneath the lower border of the digastric, and Watson and Heuter traced it between the external and internal carotid arteries to the pharynx, the seventh nerve lying above it and the ninth nerve and the stylo-hyoid ligament below it. This seems to have been the course of the canal in the very few cases that have been dissected post mortem. Some others have been traced into the same position by operation, but though a few others, like the present case, have been traced up to the thyro hyoid membrane in operation the exact position of the internal opening has not been ascertained. In Watson's case a branch of the ninth nerve innervated the walls of the pouch and in the case recorded by Berger probing of the fistula caused cough and stopping of the pulse and other symptoms of distress thought to be due to irritation of the superior laryngeal nerve. In Cavazzani's case vomiting followed the use of the probe. In most cases the walls were found to consist of fibrous tissue and striped muscular fibres have been noted by some observers. The lining epithelium was either of the stratified flattened variety or columnar and ciliated as in the present case. König noted two canals side by side, one lined with flattened and the other with columnar ciliated epithelium, and other observers have described pouches lined with flattened epithelium below and columnar and ciliated at the upper part—that is to say, the part of the pouch nearest to the pharynx.

The facts pointing to the congenital origin of pharyngeal pouches and fistulæ and to their probable connexion with the visceral clefts may be summarised as follows. 1. They are frequently hereditary. 2. They are often bilateral. 3. Though they often do not appear till early adult life they may be present as fistulæ at birth or very early in life, and it is probable that they are often overlooked, as the symptoms they give rise to are slight and may take some time to develop. 4. The peculiar course of the canal. 5. The presence of a lining of ciliated epithelium, although they are derived from a portion of the pharynx normally covered with squamous epithelium. 6. The fact that the neck of the canal or pouch often passes between the carotids in the position of the second visceral cleft. 7. The fact that striated muscle has been found in the wall of such pouches and fistulæ, and that in one case a band of striated muscle ran from the end of the pouch down the course usually pursued by complete fistulæ. 8. The fact that in several cases glands having a similar structure to the normal mucous salivary glands have been found opening into the lumen of pouches and fistulæ. This may account for the discharge noted in cases like the present One of us has met with an instance, many years ago, of a cyst, then supposed to be developed in connexion with the bursa beneath the hyoid, which was, however, lateral in position, and which it was found impossible to dissect out. The patient, who was under the care of Lord Lister, was a distinguished advocate, and he was much troubled after the operation by a mucous discharge from the fistula which occurred when he was speaking in court The fistula, after many years, closed. 9. The fact that around the lumen a considerable quantity of lymphoid tissue was noted by König in three cases and also by others, while cartilage has occasionally been met with in the walls of such fistulæ.

As this pouch was obviously of the pharyngeal variety no reference is here made to the so-called pressure pouches of the œsophagus, but it is at least possible that some of these should be placed in the same category.

FLIES AND THE SCIENCE OF SCAVENGING.

BY G. V. POORE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; PROFESSOR OF MEDICINE, UNIVERSITY COLLEGE, LONDON.

IN the recent debate[1] at the Clinical Society of London on Dr H. H. Tooth's paper[2] on Enteric Fever in South Africa it was established: (1) that the number of flies in our camps was prodigious; and (2) that these flies were largely a result of the military occupation. There seems also to have been a very general consensus of opinion (3) that flies may convey infection. It becomes therefore of great importance to consider the genesis of flies; and I trust that one who has no claims to be considered a dipterologist may be pardoned for recalling a few common facts.

Flies multiply at a prodigious rate. Given a temperature sufficiently high to hatch the eggs, their numbers are only limited by the amount of food available for them. Linnæus is credited with the saying that three meat-flies, by reason of their rapid multiplication, would consume a dead horse quicker than would a lion, and the fact that certain diptera having some outward resemblance to the honey-bee lay their eggs in the dead carcasses of animals probably led Samson and Virgil to make erroneous statements with regard to the genesis of honey and the manufacture of bees. The breeding of "gentles" for ground-bait is an industry the practisers of which could probably give much information as to the nicety of choice exercised by flies in selecting material for feeding and egg-laying. According to Packard the house-fly makes selection of horse-dung by preference for ovipositing, and as each female lays about 120 eggs and the cycle of changes from egg to fly is completed in less than three weeks it seems probable that a female fly might have some 25,000 000 descendants in the course of a hot summer. Other varieties of flies multiply, I believe, still more rapidly.

---

[1] THE LANCET, March 16th, p. 786, and 30th, 1901, p. 932.
[2] THE LANCET, March 16th, 1901, p. 769

As flies multiply upon, and in, organic refuse of every kind it is obvious that the sooner such refuse is placed where it cannot serve for the feeding and hatching of flies the more likely is the plague of flies to be lessened. The most commonly available method for the bestowal of organic refuse is burial. The egg-laying of flies in dead carcasses commences at the very instant of death, or even before death in the case of enfeebled animals. This fact has been insisted upon by Megnin in "La Faune des Cadavres" and appears to be true of human beings dying from fever. It is obvious, therefore, that there must be no delay in the burial of organic refuse and that the burial of animals and excreta is quite as important as the burial of human beings. After a great battle it may not be possible to follow this advice, but nevertheless there can be no harm in insisting that the instant burial of all organic refuse must be the aim of those who are called upon to guard the public health, whether military or civil.

It is impossible to lay down any line of action which shall be the best under all circumstances, and those who, like myself, have not been through the South African campaign are incompetent to deal with the special circumstances of that campaign. Nevertheless, I am of opinion that much that I have witnessed on Salisbury Plain in connexion with camp-scavenging is bad and is not calculated to teach the soldier the right principles of dealing with organic refuse which is always his most dangerous enemy. The science of scavenging requires to be taught. If the duty of scavenging be left to the ignorant and be controlled by persons who think that necessary details are beneath their notice then annoyance and disease are the only results possible.

If the scavengings of a camp are to be satisfactorily dealt with the question of their ultimate disposal must be ever present in the mind of the scavenger. The materials collected have to be burnt, to be buried, or to be otherwise dealt with. The mere dumping of refuse in mixed heaps ought certainly to be abandoned and the contents of the latrines ought to undergo immediate superficial burial at the nearest available spot in order to avoid cartage and spilling. In many cases it should be possible to bury the excreta in the immediate vicinity of the spot where they are dropped. We hear of excreta being buried in trenches 10 feet deep, but such a course must mean that they are left exposed to give off odours and to breed flies for many hours before they are under ground and covered up. I have consulted a gravedigger on this question and asked him, "If you were ordered to dig a grave 10 feet deep what breadth and length would be necessary and what time would you require?" His reply was that (in chalk) the grave would have to be six and a half feet long and three and a half feet wide, and that he would require a day and a half to complete the work. It is certain that 36 or 48 hours' delay in the disposal of fæces is most undesirable. I have always advocated the burial of fæces in shallow furrows rather than in deep trenches, and, in this country at least, where alone I have had experience, I am convinced that this is the only reasonable course to pursue. If properly done all offence to eyes or nose is thus ended and the fæces cease to attract either flies or rats. The fæces can be covered continuously as soon as they are dropped and there is no need of having malodorous open trenches partially filled which are waiting to be completely filled before being covered up.

This burial of fæces must be done methodically and carefully and with every attention to detail. The proceedings must be precisely those of a gardener who is intent upon raising crops. The fact that in war the crops may never be harvested is quite beside the mark and affords no excuse for slovenly procedures which are a danger to health Nitrification in the soil is the aim equally of the sanitarian and the agriculturist. If a plot of ground 50 yards long and 50 yards wide—slightly more than half an acre—be allotted for the disposal of fæces this should be marked off into, say, 16 strips, each about eight feet wide and 50 yards long, with a narrow path of about 18 inches between each strip to allow for watering and cultivation. The line of the furrows must be accurately marked by a cord and reel in the ordinary way, and the digger must move continuously backwards in order to avoid trampling on the freshly dug ground. The making of the furrows should commence at the point furthest from the latrines and it should gradually come nearer to them. The earth removed from the first furrow should be wheeled down near the latrines where it will be ultimately wanted to cover the last furrow which is dug. The capacity of the furrow or little trench will depend upon the size of the spade I find that, working in ordinary garden soil with a spade having a blade nine inches long and seven inches wide (the furrow being consequently nine inches deep and seven inches wide), eight stable-bucketfuls of soil each holding two and a half gallons, or about 22 pounds weight of earth, were removed. This amounts to two and a half bushels of soil, weighing 176 pounds, as the measure of the capacity of a trenchlet eight feet long. This trench must be filled with excreta and great care must be taken that nothing except fæces and paper and the accompanying urine is placed in it If broken crockery or old tins are accidentally mixed with the excreta they must be removed. The trench being filled with fæces, mark out a digging line at a distance equal to the width of the spade (seven inches) behind the edge of the first trench and then cover the fæces in the first trench by the earth removed in making the second. Owing to the draining away of urine and moisture and their great compressibility it will be found that the excreta undergo a considerable diminution of bulk when tipped into the trench. When the earth of the second trench has been removed and shovelled on to the top of the first trench it will be found that there is a raising of the general level of the ground and the second trench will be found to have a cross section which is rather triangular than rectangular owing to the oblique direction of its front wall which is composed of a sloping bank of friable earth. The surface of the ground must be left crumbly, smooth, and perfectly neat, like a well-prepared garden bed. No particle of fæces or paper must be left uncovered. There will be no offence to eye or nose, no putrefaction is possible and the fæces are beyond the reach of dipterous insects, and if there has been no delay in the collection and burial of the fæces they cannot have been used for oviposition to any great extent, so that the soil will not become infested with "grubs."

How many men will provide the quantity of fæces which can be placed in a trench eight feet long from which 176 pounds weight of earth have been removed? The answer to this question is governed by bulk rather than by weight. If fæces and earth were equal in bulk for equal weights and if we allow a quarter of a pound of fæces for each man—for the urine soaks away and *quâ* bulk may be neglected—then the answer would be 176 × 4 = 704. If the fæces are weight for weight four times as bulky as the earth, the answer is 176. In any case it seems safe to say that a trench eight feet long, nine inches deep, and seven inches wide will suffice to take the fæces of 100 men. This estimate entirely accords with my experience gained in my garden at Andover where the fæcal accumulations of 20 cottages have been disposed of daily in the manner indicated for 18 years and where it takes at least five years to cover an acre of ground in this way. Those who have not had experience of this method of dealing with fæces are apt to have exaggerated views as to the amount of land required. If a trench eight feet long and seven inches wide is sufficient for the disposal of the daily quota of excreta from 100 men, then 10 such trenches occupying an area of eight feet by 70 inches—say six feet—is enough for 1000 men and one strip of ground 50 yards long and eight feet wide would serve for a regiment of 1000 men for 25 days, and the 16 strips would serve for 400 days—let us say half an acre per annum per 1000 men. The actual area necessary will depend to some extent upon the nature of the soil and the care and skill of the scavenger, but in no case can the area required be regarded as a bar to the process—certainly not on the veldt or on Salisbury Plain. It need not be insisted on that a scavenger must be incessantly at work. The excreta should be taken up as soon as dropped and be placed in a covered pail, and the pail when full should be emptied into the furrow and covered up. In this way effluvia are stopped and ovipositing by diptera is rendered impossible. Further, this method of disposing of fæces necessitates no increase of the impedimenta of an army; no lime or chemicals are needed and no apparatus beyond a spade and a set of garden tools.

The ground beneath which the fæces are deposited should when the work is done have the appearance of a well-prepared garden bed and it will need a little attention until it is covered with herbage of some kind. The only question remaining to be decided is as to what that herbage should be. There can be no camp without water-supply, and in every camp one of the sanitary problems is the disposal of waste water. Some of this waste water should be used in time of drought for laying dust and encouraging fertility in that small area of ground beneath the well-tilled surface of which the fæces are safely bestowed. Then, the higher the temperature the quicker will the ground bring forth green leaves to freshen the air. Whether the crop be grass, cabbage, cereals, onions, mustard and cress, lettuces, spinach, or what not must depend upon circumstances. I think the seeds sown in such ground should always be those of culinary vegetables which may prove a real blessing if the camp be long occupied. With a little care in a hot climate one may have a green covering of grass or mustard and cress in a week which at least will give off oxygen to the air even if it do not serve as an anti scorbutic diet for man and beast—a diet which may just supply that something which is lacking in tinned and salted provisions

In a temporary camp these methods of excrement disposal are the best on the grounds of immediate hygiene In places like Salisbury Plain which are to be used as camping grounds year after year, latrine gardens are essential and, if properly managed, should furnish a good many acceptable extras for the canteens. Last year at Perham, on Salisbury Plain, there was a field of many acres occupied by the scavenging contractor and placed a few hundred yards from the camping ground On this were piled heaps of camp refuse, old tins, meat bones, broken victuals, packing materials, and fæces which had been "dumped" with a view to burning when dry enough. In their recent state these heaps (in which flies were swarming) could be smelt for a quarter of a mile down wind and when they began to burn the offensive smoke drifted still further and not seldom over the camps themselves This haphazard method of "dumping" refuse in pestiferous heaps is not economical, not even from the point of view of the area of ground required, and would be rendered unnecessary by a little care in collection and the judicious use of the spade by men who knew how to turn these despised materials to profitable account Horse-dung in the same way should be neatly stacked in heaps like hotbeds, protected at the sides and covered with earth In this way the flies would be prevented from feeding and egg-laying on the dung, large quantities of saladings might be produced, and when the camp was moved this well rotted material should be applied to the camping ground with a view to the renovation of the turf. On Salisbury Plain the growth of summer is trodden under foot and there is no systematic renovation in the winter On turf downs the actual camping ground should be changed every year and the ground "top dressed" as soon as the camp breaks up in the autumn. Without careful management and good husbandry these downs will soon be trampled and scuffled into a dusty wilderness. In the same way all the kitchen refuse should (after utilisation to a maximum extent in the stock-pot, &c) be neatly stacked, protected at the sides and covered with earth. All organic refuse should be completely protected by soil from the attacks of diptera and its fertilising properties should be utilised forthwith

It is sometimes said that we ought to be ready to forgive the house flies for the annoyance which they cause to us because of their great services as scavengers; but I am rather inclined to take the view that the presence of flies is a reproach to us for not putting organic refuse to its proper use and that the fly is a robber which has been bred in material which we have deliberately allowed to lie above ground instead of covering it with soil The scrupulous sweeping up of crumbs and food particles immediately after meals and the instant removal of the remains of food to fly-proof larders need not be insisted upon I believe that a great advance in domestic hygiene will have been made when the custom is more general of removing dung every day from our stables, piggeries, cattle-sheds, and poultry-runs, and stacking it carefully so as to prevent the access of diptera, or burying it immediately beneath the surface of well-tilled soil with a view to the production of crops We pity the horse "turned out" in a paddock when we see it tormented with "flies" Few of us pause to think that if the horse dung had been collected daily and put to more profitable use instead of being allowed to lie about and generate a plague of flies the animal might have been happier and the dung might have been more valuable for fertilising purposes When flies breed in dung-heaps the larvæ eat the dung and leave the straw If each fly needs one grain only of sustenance then the 25,000,000 which I have stated as the possible season's progeny of a female house fly will be capable of robbing a farmer of 25,000,000 grains of fertilising material, which at 7000 grains to the pound works out at 3571 pounds, or considerably more than one and a half tons. It is bad economy to have your scavenging done by flies and sad to see your potential wealth make to itself wings and fly away. In my garden at Andover where human excreta have undergone daily superficial burial for about 18 years there is no excess of flies and I have come to the conclusion that an essential part of garden management is the daily collection of all garden offal, such as dead leaves, fallen and rotten fruit, &c., and either superficially burying or stacking it so that it shall not serve as a breeding-ground for insects which often prey upon the plums and peaches in the autumn

In the management of refuse I am no advocate for the use of chemical disinfectants These are expensive, generally evil-smelling, often poisonous, and lead to an increase of material to be transported The soil is quite capable, with proper management, of turning all organic refuse into "soil"—a fact which the experiments of Sir Seymour Haden and myself have abundantly proved. Our experiments have also shown that from the point of view of the innocuous transformation of organic refuse into "soil" deep burial is a mistake This is true alike of dead animals and of excreta We are happily hearing less of the pollution of the earth and of the growth of microbes and toxins in the soil and even from the laboratories of bacteriologists we are learning that the soil is our best friend. The use of quick-lime in the treatment of excreta is, I believe, quite unnecessary My experiments in burying small animals tend to show that the quick-lime preserves the body and mischievously prevents the beneficent action of the soil In the management of refuse there must be no slovenly "dumping" What is wanted is proper sorting at the time of collection great attention to detail, absolute neatness, and an appreciation of the ends to be attained

In recommending the immediate collection of all organic refuse and its instant covering with earth I am making no new recommendation Moses had had experience of a "plague of flies" in Africa and was no novice in the matter of camp-management He found it necessary to be most explicit in his directions for the treatment of excreta. These directions are given in Deuteronomy xxiii , 12–14, and I find that in the revised version of the English Bible there is an interesting change in the passage. The old version runs thus:

> Thou shalt have a place also without the camp, whither thou shalt go forth abroad:
>
> And thou shalt have a paddle upon the weapon, and it shall be, when thou wilt ease thyself [sittest down] abroad, thou shalt dig therewith, and cover that which cometh from thee:
>
> For the Lord thy God walketh in the midst of thy camp, to deliver thee, and to give up thine enemies before thee; therefore shall thy camp be holy: that he see no unclean thing in thee [nakedness of anything] and turn away from thee

The new version says (verse 13): "Thou shalt have a paddle *among* thy weapons," and as a variant for paddle gives "shovel" in the margin The passage, therefore, means that a shovel for burying excreta immediately is a necessary implement in every camp

Portland-place, W.

A CASE OF

SYMMETRICAL RETINAL DETACHMENT OCCURRING DURING LABOUR AND ASSOCIATED WITH ALBUMINURIA RESULTING IN COMPLETE RECOVERY.

BY REGINALD G. HANN, M R C.S ENG , L R C P. LOND ,

AND

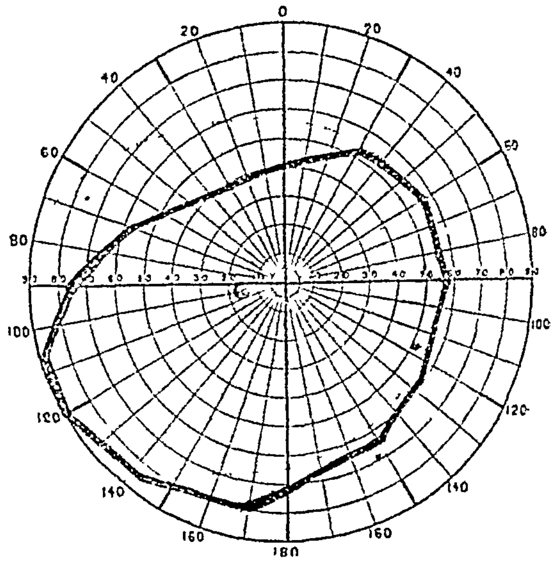
R LAWFORD KNAGGS, M C CANTAB , F R C S ENG.

THE onset of sudden blindness during labour is a symptom which would naturally excite attention, but perhaps from the fact that a large majority of these cases recover vision and from the attendant circumstances the ocular conditions are not often investigated at the time. This no doubt accounts for the paucity of recorded cases One cause of blindness during labour is retinal detachment in association with general œdema or eclampsia. The connexion of these two conditions with renal disease is generally accepted, but retinal detachments occurring during labour run a very different course from that of detachments occurring in the course of renal retinitis. The former end in recovery; the latter are usually a prelude to a fatal issue. The following case is a contribution to the subject.

The patient was a woman, aged 21 years, who, with the exception of scarlet fever in childhood, had had no illness until her first confinement on Nov. 25th, 1900. When first seen she had been in labour for 24 hours; the pains were severe and prolonged, recurring at intervals of about five minutes. There was œdema of the face, hands, feet, and legs, and according to the friends this had been present for about three weeks. For three hours the pains continued with great intensity, then the patient fell into a state of semi-coma with stertorous breathing, from which she would be roused by the pains; shortly before the onset of this condition she complained of inability to see, and from her actions it was obvious that she was quite blind. So far as could be gathered this blindness was of sudden onset. Forceps were now applied and the labour was terminated. The following day she remained semi-comatose, and for 30 hours from the birth of the child no urine was secreted. On the 27th she was conscious, dull, and lethargic, and she passed a small quantity of urine containing much albumin, though owing to the puerperal state this observation is of uncertain value. Under atropine an ophthalmoscopic examination of the eyes was made. In both very large and obvious detachments filled up the lower third of each globe. They were symmetrical in appearance and bilobed in outline, owing to a depression in the middle. They floated up readily on the slightest movement of the eye and had all the usual characters of detached retinæ. The discs, which were just clear of their summits, had defined edges, but were surrounded by an œdematous pallor. Though the patient was to all intents and purposes blind it was elicited that some kind of vision was present, but she was too drowsy and too easily tired for prolonged examination. Her general condition after this date rapidly improved; the œdema all disappeared in the first week, the drowsiness passed away and she became brighter and more intelligent. During the whole period that she was under observation, however, a trace of albumin was always to be found in the urine. On Dec. 22nd an examination of the eyes was made, the pupils being dilated with atropine. The retinal detachments were no longer to be seen. Close to the ora serrata in the lower part of the right globe it was just doubtful if the retina was yet completely reapplied. Through the retina at this spot, however, pigment patches could be seen and if any projection of the retina that could be called detachment existed it was evident, notwithstanding the difficulty of examining a part so far forward, that it was very trivial. With this qualification it may be stated that both detachments had completely disappeared. The edges of the discs were slightly blurred and swollen, but their physiological cups were well marked. There was very slight tortuosity of some of the vessels. Scattered over the fundus in both eyes was a general but an irregular distribution of pigment granules, spots, and patches, and the latter in places, and especially in the right macular region, were confluent The pigment spots were much deeper in colour than were the patches. Vision: right eye with + 1·5 D = $\frac{6}{18}$; left eye with + 1 5 D. = $\frac{6}{12}$ (one letter). The fields showed definite symmetrical contractions in the upper hemisphere—no doubt due to impairment of function dependent upon the recent detachments. The urine was acid and of specific gravity 1012. A ring of albumin was observable and there was a trace of sugar (?) No casts were found. Jan. 8th 1901 —Vision: right eye = $\frac{6}{9}$ (two letters); left eye = $\frac{6}{9}$ (several letters). No improvement could be gained by glasses. On the 9th, with the pupils widely dilated with homatropine, it was seen that all traces of the remnant of the detachment in the right globe had completely gone. The fields were unaltered, still showing the limitation in the upper hemispheres.

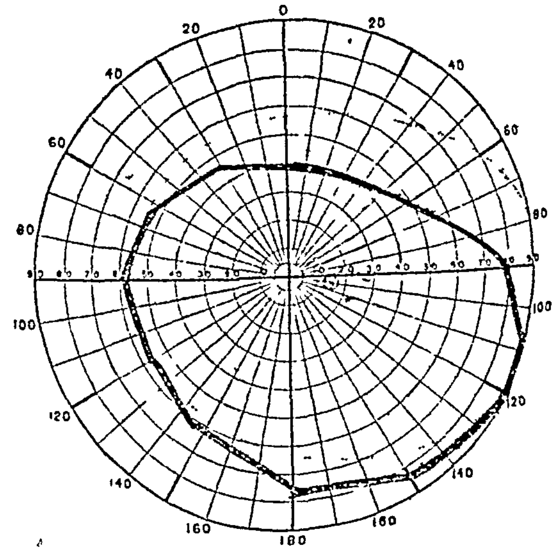
In this case the influence of labour in producing the detachments was unmistakeable. Under less trying circumstances the interior tunics of the eye are probably protected from the œdema which is present in the other tissues by the intra-ocular tension. During the labour pains the return of the venous blood must be retarded and a considerable back pressure must be put upon the capillary circulation. For three hours at least before the development of blindness in the case recorded this intermittent retardation had been going on every five minutes, and though no increase of the general anasarca was noticed—a point that might easily escape observation—it is not difficult to imagine that, so far as the eyes were concerned, the relation between the intra-capillary and intra-ocular tension was so modified as to lead to an effusion of serum into their tissues. This effusion must have been far more copious in the choroid than in the retina, owing to the very great difference in vascularity between the two structures, and the fluid poured out behind the retina and gravitating, as is customary, to the lower part of the globe, would float the retina up upon its surface. With the passing away of the exciting cause the natural relation between the blood-pressure and the ocular tension would return, absorption of the dropsical fluid would take place, and the retina would become reapplied. Given the general tendency to œdema dependent upon the renal disease the mechanical conditions affecting the circulation induced by the strains of the labour were probably quite sufficient to account for the detachments. There is no reason to suppose that there was any renal retinitis present. Nothing that could be described as such was noticed on the second day after delivery, and the alterations in the fundus seen at a later date were doubtless the result of the disturbance to which the choroid and retina had been subjected.

FIG. 1.



Perimeter of right eye.

FIG. 2.



Perimeter of left eye.

We are aware of only one case that definitely resembles the one just related. It is recorded by Adamuk. In it binocular detachments occurred during severe eclamptic attacks in the eighth month of pregnancy. Premature delivery was followed by spontaneous recovery.[1]

In a clinical lecture, on "Pregnancy Nephritis" Dr. Reginald Southey[2] has recorded a case of detachment of the retina occurring about the time of delivery which forms a most instructive contrast to the foregoing case. A domestic servant, aged 23 years, was admitted to St. Bartholomew's Hospital with general dropsy of three weeks' duration. There was albuminuria and in the course of a week she had become nearly blind, both discs being swollen and red. Five days after admission (Feb. 14th, 1882) she was delivered of a dead fœtus, "but in consequence probably of labour pains and straining there was slight hæmorrhage in each upper eyelid and the conjunctivæ were very œdematous" On Feb. 18th there was found in the right eye a patch of white effusion near the disc and extensive detachment of the lower half of the retina in the form of three large cusps In the left eye were two hæmorrhages. On March 6th no trace of the detachment in the right eye could be discovered, but there were optic neuritis, several patches of effusion here and there, and some pigmentation which was most marked where the detachment had been. The albuminuria disappeared a week after delivery and the patient was discharged well on March 15th with no complaint about her sight and able to read the daily papers.

Now *the blindness* in Dr. Southey's case did not come on suddenly during labour but had been gradually increasing for nearly a fortnight before. It was apparently due to well-marked albuminuric neuro-retinitis which was most advanced in that eye in which the detachment subsequently formed. The part that the actual labour played in the production of the detachment is open to question, but whilst the latter soon disappeared, the retinitis, for a time at least, got worse. Though there were no eclamptic seizures, and from Dr. Southey's account the pains can hardly have been either severe or prolonged, it is nevertheless probable that the latter were sufficient to lead to the detachment in that eye in which the more profound inflammatory changes had prepared the way. In our case the pains were severe, and the detachments were symmetrical, but there was no albuminuric retinitis. From this it will be seen that we incline to the mechanical explanation of the detachments, whether inflammation of the retina is present or not, and regard retinitis as a predisposing cause, but the labour as the exciting one.

Ophthalmic surgeons must be familiar with cases in which a history is given of eclamptic attacks and of blindness following confinement and ending in recovery. These cases are rarely investigated at the most interesting period and when they are subsequently seen there is probably nothing found to explain what the exact condition was. Possibly detachments of retinæ or suddenly developed œdema of the choroid and retina may explain some of them. The following is a case in point. A woman had to have her first pregnancy terminated between the sixth and seventh month for puerperal eclampsia After her confinement she was quite blind for four days. She had gorgeous visions of various colours and there was an instantaneous shifting from lightness to darkness; then sight gradually returned. The albuminuria disappeared a few days after the confinement. A year later beyond a little grey haze about both discs and slight tortuosity of the vessels there was nothing abnormal to be seen.

Leeds.

[1] Abstract, Knapp's Archives of Ophthalmology, vol. xx., p 457.

[2] THE LANCET, Jan. 13th, 1883, p. 47.

ROYAL MINERAL WATER HOSPITAL, BATH.—The annual meeting of the subscribers of this institution was held on May 2nd, under the presidency of Colonel Vaughton-Dynnock. The one hundred and fifty-ninth annual report stated that owing to extensive alterations in the building the greater number of beds had been closed since August last and the number of in-patients had been limited to 50. The financial statement showed that the expenditure had exceeded the income. The report added that an appeal had been made to the public for the necessary funds, which were estimated at £6000, to meet the expense of the necessary alterations, but only £450 had been received in response, so that the committee are compelled to use some of their capital for the purpose. Mr. W. Kemble was elected President.

IS THE MURMUR OF MITRAL STENOSIS SYSTOLIC OR PRESYSTOLIC IN RHYTHM?

BY HUGH WALSHAM, M.A., M.D. CANTAB., F R.C P. LOND,
PHYSICIAN IN CHARGE OF OUT-PATIENTS TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

AS a student I was taught, and I believed, that the murmur of mitral stenosis was presystolic in rhythm. I read M. Fauvel's paper on the subject in the *Archives Générales de Médecine*;[1] I applied what I there read to as many cases of mitral stenosis as I had the chance of examining; and I satisfied myself that the thrill and murmur were really presystolic. It was therefore with somewhat of a shock that I read Dr. W. H. Dickinson's paper published in THE LANCET of Oct. 1st, 1887, p. 650, entitled, "Remarks on the Presystolic Murmur, Falsely so called." I read this interesting paper carefully and was almost convinced but not quite.

It is not my intention in this paper to go over the ground again, at least from the same standpoint. It appeared to me that the Roentgen rays might possibly be able to settle the question. I thought what the sense of touch and hearing was unable conclusively to synchronise the addition of that of sight might. Since the installation of the Roentgen-ray apparatus in the City of London Hospital for Diseases of the Chest I have examined, as a matter of routine, all my cases of mitral stenosis with the x rays, and have, I venture to think, learned much thereby as to the rhythm of the thrill and murmur of this variety of valvular disease. It will be well, however, before discussing the question, to describe shortly what is seen of the action of the normal heart on the fluorescent screen. The shadow of the normal heart shows changes of form synchronous with the rhythmical contractions of the organ. The movement of the apex, when this is well seen, is always a heaving movement which carries the apex somewhat rapidly towards the left, followed by a retreat more rapid still towards the middle line. It is not the apex of the cardiac shadow, however, as we should have thought, that presents the greatest displacement, but the middle of the left border corresponding to the ventricular cavity at a point where it crosses the shadow of the fourth left rib. The displacement of the left border of the cardiac shadow manifestly corresponds to the alternate systole and diastole of the organ. If with these movements before our eyes we auscultate the heart by means of a flexible stethoscope we can satisfy ourselves that the first sound of the heart corresponds to the exact moment when the movement of projection of the cardiac shadow towards the left gives place to its immediate retreat towards the middle line. The projection towards the left is therefore clearly presystolic and corresponds to the systole of the auricles, while the movement of retreat corresponds to the systole of the ventricles. After this movement of retreat comes a slow and progressive distension of the shadow of the ventricular wall, only occasionally seen, which corresponds to the period of repose of the organ. Then begins anew the brisk projection of the shadow towards the left during the systole of the auricles. Professor Potain has observed that this projection of the cardiac shadow coincides with the external phenomena of the impulse as perceived by inspection and palpation of the præcordial region. There can be, I think, no question that the visible impulse, distinct from the brisk shock which follows it, is a presystolic phenomenon, due to the systole of the auricles and to the consecutive distension of the ventricles. Radiography demonstrates in some cases beyond question that the position of the shadow which really corresponds to the apex of the heart is obviously below the point of cardiac impulse against the chest wall. The contour of the shadow of the right side of the heart when it projects beyond the sternal and spinal shadow shows movements of the same rhythm as those of the ventricular line. So much for the normal heart as seen beating with the screen.

I will now pass on to the heart of mitral stenosis. In a well-marked case of so-called pure mitral stenosis if the hand be placed over the præcordial region at the point of maximum intensity of the thrill (and this can be done without obliterating the shadow of the heart on the screen) and the cardiac shadow be watched, we find that the thrill corresponds to the advance of the left border of the shadow of the heart to the left and ends abruptly with the retreat of the shadow towards the median line—that is to say, the thrill is obviously presystolic in rhythm and ends with the systole. It begins with the advance of the left border of the cardiac shadow to the left—that is, during the auricular systole—and ends with the retreat of the shadow towards the middle line—that is to say, with the ventricular systole. Again, if while watching the heart with the screen the chest-piece of a binaural stethoscope be placed on the screen at the point of maximum intensity of the murmur (previously determined) it will be found that the murmur begins at the moment when the shadow of the left ventricle is advancing to the left—that is, during the auricular systole—and ends abruptly when the shadow retreats towards the middle line—that is, with the ventricular systole. I have examined a good many cases of pure mitral stenosis with reference to this point and have convinced myself that the thrill and murmur are truly presystolic in rhythm.

---

[1] Archives Générales de Medicine, 4e série, tome I., p. 1, 1843. The original paper on the subject.

It is very interesting to go through the correspondence in THE LANCET that followed the publication of Dr. Dickinson's paper. Dr. Graham Steell, in a letter on the subject on Oct 15th, 1887, p. 784, came very near to a solution of the question. He says: "Dr. Dickinson states that he has found that the presystolic murmur begins with systolic (i.e, ventricular?) movement, but such movement does not necessarily imply contraction. It seems very likely that there will be some movement communicated to the ventricles by the contraction of the auricles." This is exactly what happens.

Harley-street, W.

OPO-THERAPY IN GYNÆCOLOGY.

BY JOHN PHILLIPS, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,
OBSTETRIC PHYSICIAN TO KING'S COLLEGE HOSPITAL AND LECTURER ON
PRACTICAL OBSTETRICS IN KING'S COLLEGE; EXAMINER IN
OBSTETRIC MEDICINE TO THE ROYAL COLLEGE
OF PHYSICIANS OF LONDON.

OPO-THERAPY, which seems a preferable word to organotherapy, was created by Landouzy to designate the science which treats of curative elements found in the "internal secretion" of certain ductless glands. As the latest craze seems to be the treatment by animal extracts it behoves us carefully to consider whether there is any real ground for supposing that such treatment is efficacious, and if so on what lines and in what manner it should be carried out. The three extracts which must be considered would appear to be (1) thyroid extract; (2) ovarian extract; and (3) extract of the mammary gland

1. In considering the first it need only be said that ample clinical evidence shows that certain nutrition disorders associated with pelvic disturbance are undoubtedly benefited by this treatment; moreover, the dose of the drug is known and its toxic effects are recognised. It is certainly of value in amenorrhœa so often found to accompany extreme obesity and as a complication of myxœdema; according to some authorities it is beneficial in the hæmorrhages of fibroid tumours of the uterus.

2. In considering the treatment by ovarian extract much difficulty must be encountered at the onset as we are dealing with a drug the dosage and the toxic effects of which are so far quite an unknown quantity. Dr. Régis[1] seems to have been one of the earliest authorities to record the use of ovarian juice. He prescribed it in a case of mania following removal of both ovaries and tubes; the result was most successful although many injections were necessary. Leopold Landau[2] gives his support to this mode of treatment, and since then many original articles (with detailed observations) have been written recommending its adoption in increasingly numerous varieties of female disease.

The methods of administration of ovarian extract appear to be three: (1) that followed by Knauer who grafted the fresh gland into the peritoneum or under the skin;[3] (2) Brown-Séquard's method by subcutaneous injections of the organic extracts; and (3) the method recommended by Horwitz and others and now in general use—viz., administering the extract by the mouth or the rectum, either in a natural state, in the form of "ovarine" tabloids, or as a glycerine extract. With the thyroid extract both dose and toxic effects are well known, but so far no satisfactory evidence has been brought forward as to the effects of ovarian extract. Five-grain tabloids have been given as a rule thrice daily, and I have prescribed as many as three tabloids thrice daily without any toxic effects or any amelioration of the symptoms arising. Jayle has observed zona and Schuster general urticaria after prolonged ingestion of ovarian extract. I saw one case of the latter, of which there was no doubt, but I am strongly of opinion that the rash was due not to the drug but to some impurity in the vehicle of administration. I have given ovarian extract in many diseases (often experimentally), but in none have I obtained any definitely satisfactory results, with the exceptions of the natural and the artificially induced menopause. In eight cases of menopause the distressing headaches and flushes were certainly relieved, but whether this was the possible result of suggestion or not I am unable to say; Krusen,[4] after a three and a half years' experience, is of a somewhat similar opinion. He says that in the treatment of amenorrhœa and dysmenorrhœa it is useless and he noticed no appreciable result in its exhibition during the natural menopause. He thinks that the best results in opo-therapy are attained by the use of the thyroid and adrenal glands and that the ovary in function is in no sense analogous to these organs. Jullen[5] finds the drug, on the contrary, of great value in post-operative menopausal symptoms, in amenorrhœa, dysmenorrhœa, anæmia, and chlorosis, and osteomalacia. He gives full notes of 41 cases in support of his assertions.

3 The administration of mammary abstract is surrounded by still greater uncertainty. It is best given in the raw state, cow's udder being cut into thin slices and made into a salad. This method has been frequently prescribed and carried out by Freudenberg.[6] No toxic or other effects beyond a suspicion of improvement in lactation during its ingestion have been recorded.

Brook-street, W.

SOME QUESTIONS WITH REGARD TO ACUTE MIDDLE-EAR INFLAMMATION.

BY P. McBRIDE, M D., F.R.C.P., F.R.S. EDIN.,
SURGEON TO THE EAR AND THROAT DEPARTMENT, ROYAL INFIRMARY,
EDINBURGH; LECTURER ON DISEASES OF THE EAR, THROAT,
AND NOSE, EDINBURGH UNIVERSITY.

THE fact that some unsolved problems still remain with regard to acute middle-ear inflammation was very forcibly brought home to me by the following case.

A man, aged 48 years, consulted me on Jan. 12th of this year giving the following history. On Dec. 21st, 1900, he had a nasal and bronchial catarrh; pain in the left ear came on 10 days later, followed by a free discharge of matter. When I examined him the hearing on the right side was fairly good, but a watch normally heard at 30 inches was not perceived by the left ear when pressed against it, and words spoken in an ordinary tone could only be distinguished when uttered quite close to the auricle. On examination after the removal of the discharge a small pouting perforation was seen above the middle of the membrane, which was, as is usual in these cases, red and bulged, while the malleus was invisible. Air passed through the perforation readily, and after the parts had been freed as much as possible from discharge the patient could hear an ordinary voice across my room. Examination of the anterior nares revealed no abnormality, but on posterior rhinoscopy I saw some pus in the right choana, while about the middle of the septum there was symmetrical thickening—a condition which I meet with so frequently that I do not attach any importance to it. The presence of pus, however, seemed to me to be important and it at once suggested the possibility of an affection of one of the accessory cavities of the nose, although I recognised that it might be due to the remains of a severe pharyngitis. I syringed out the ear with carbolic solution and plugged it with sterilised gauze. On Jan. 14th, 1901, the gauze was dry, but on blowing by Valsalva's method pus came through the perforation which seemed to have contracted. My watch was heard in contact, but a low conversational voice could only be heard quite near the left ear. I passed the Eustachian catheter, not caring to risk the use of Politzer's method for fear of driving pus up the Eustachian tubes. It will be noted that I allowed the patient to perform Valsalva's experiment at the beginning of this visit, but I think that this was a mistake as it might have resulted in infection of the other ear. I noted that the teeth in the upper jaw were bad, and the patient told me that he had long complained of something dropping into the right side of his throat. As a repetition of the plugging would probably have led to closure of the perforation without cessation of exudation I ordered him to syringe the ear with sterilised boric solution and to dry out with sterilised wool. After this I passed the Eustachian catheter once or twice, but no improvement resulted. On the 22nd there was a little tenderness over the tip of the mastoid and the perforation had further contracted. All through the membrane had tended to bulge and under these circumstances I enlarged the opening by free incision, having first applied Bonain's mixture (carbolic acid, menthol, and cocaine) On this visit transillumination showed the right antrum of Highmore to be opaque. There remained, therefore, little doubt that there was empyema of this cavity and that the pus in the right choana proceeded from it by way of an accessory opening. I have frequently met with such cases in which no pus appeared in the middle meatus as seen by anterior rhinoscopy and in which the first indication was afforded, as in this instance, by the results of posterior rhinoscopy.

I need not follow all the tedious details of this case from day to day. Suffice it to say that while the mastoid pain abated and the discharge became more abundant the perforation gradually diminished in size and again tended to present that pouting appearance which is of such unfavourable significance in these cases. Having made sure of the existence of pus in the right antrum of Highmore I proposed to delay having it attended to until the ear healed. The latter, however, not only showed no signs of healing, but looked very much as if its condition would necessitate draining through the mastoid. While quite recognising that possibly the empyema of the antrum was the original source of infection I failed to realise its importance as a factor in keeping up the middle-ear suppuration. It was more because draining the cavity could do no harm, and if, as I expected, a mastoid operation should become necessary I would rather operate without the presence of pus in the maxillary sinus, that I finally, on Feb. 21st, recommended that a dentist should be asked to open the antrum of Highmore and to insert a plug. I may mention that in the first instance I always have my cases treated in this way, as a good dentist is perfectly capable of making a satisfactory opening and is able to introduce a neatly-fitting plug which the patient can readily learn to put in and take out. If subsequently a larger opening followed by curretting, or a counter opening into the nose, becomes necessary I carry out these proceedings myself. In the case of the patient under consideration pus was evacuated, but after a few days the liquid syringed through was found to be clear, showing that probably the antral suppuration will speedily subside. The operation was performed on the 22nd, and on the 24th the hearing began to improve. On the 26th there was practically no discharge. On March 5th he could hear a whisper across my room and the membrane was beginning to resume its normal colour; while on the 11th a low whisper was perceived at 18 feet, and the membrane was proved to have definitely healed.

I have given this case in some detail, not only on account of its interest, but also because its consideration seems eminently adapted for raising several important questions with regard to acute middle-ear inflammation. These I shall treat shortly *seriatim*.

1. *The connexion between acute otitis media and affections of the nose and naso-pharynx.*—It is of course perfectly well known that acute nasal or pharyngeal inflammation may lead to suppuration of the middle ear. It is also known that marked adenoids, and possibly much enlarged inferior turbinals, may predispose to the affection. It is, however, not sufficiently recognised that there is a form of adenoids which practically produces no other trouble but which may be responsible for recurrent attacks. In these cases the patient breathes perfectly; he may be subject to colds in the head but they do not attract much attention. On examining with the rhinoscopic mirror, however, a layer of adenoid tissue is observed occupying the space between the Eustachian orifices and apparently pressing upon their margins. On digital examination the lymphoid tissue will be felt, but it will be observed that there is not any great quantity present. In such cases, however, the recurrent acute ear attacks will usually cease after the adenoid tissue has been removed. The relation between empyema of an accessory cavity and acute middle-ear inflammation has not, I think, been hitherto more than incidentally alluded to. The instance above described shows a very distinct connexion, as it is hardly conceivable that the rapid cure of a case which until the antrum of Highmore had been opened seemed going from bad to worse was merely a coincidence. It is of interest to note that the empyema of the antrum was on the right side, while the ear affection was on the left. It seems obvious that in some way the presence of free pus in the right choana affected the opposite ear, but I do not think that the *modus operandi* will repay speculative discussion.

2. *What is the best method of treating middle-ear inflammation after spontaneous or artificial perforation has occurred?*—I do not think that the new method of plugging the meatus with aseptic dressing after so far as possible sterilising the canal is at all suitable for all cases. In this instance the perforation certainly diminished in the two days during which such dressings were applied and, as it appeared to me, on account of their application. In future I shall adopt this method with great caution, if at all, when the perforation is small and the membrane tends to bulge. It is of course now the custom to decry the use of Politzer's bag and even the catheter in all cases while suppuration is still going on. In the instance just described the former was certainly contra-indicated because of the presence of pus in the right choana and possibly there was some risk in employing even the latter. In the average patient, however, where there is no recognisable infective secretion in the nose or naso-pharynx and where drainage is difficult owing to the small size of the perforation I am still inclined to advocate both methods. If they seem actually beneficial I am not disposed to be deterred from their use because they are hypothetically or even theoretically dangerous.

3. *When should the question of mastoid operation be considered?*—There are two conditions which, after perforation has occurred, seem to me to indicate that the case will be troublesome—to wit, (1) excessive discharge, and (2) a small perforation in a bulged membrane. When the discharge appears in such quantity that it is hardly conceivable that it can be all secreted by the lining membrane of the tympanum it will usually be found that after a varying period some tenderness, or even spontaneous pain, arises in the mastoid region. If then Schwartze's operation be performed it will often be discovered either that the whole process is more or less softened and infiltrated with granulations or that the antrum is large and contains much pus. The former is the more common and in my experience it is a frequent complication in influenzal otitis.

In the presence of a small pouting perforation and a bulged membrane, such as existed in the case recorded, the surgeon is often in great difficulties as to how best to obtain drainage. A free incision is valuable for the moment, but, as every experienced aurist knows, it soon closes and the condition is no better than before. The least indication of mastoid inflammation will give an excuse for operating and I believe that, given the above condition of matters persisting after other remedies have had a fair trial, this excuse should in the interests of the patient be taken immediate advantage of. It is, indeed, an open question whether the occurrence of pain should be awaited.

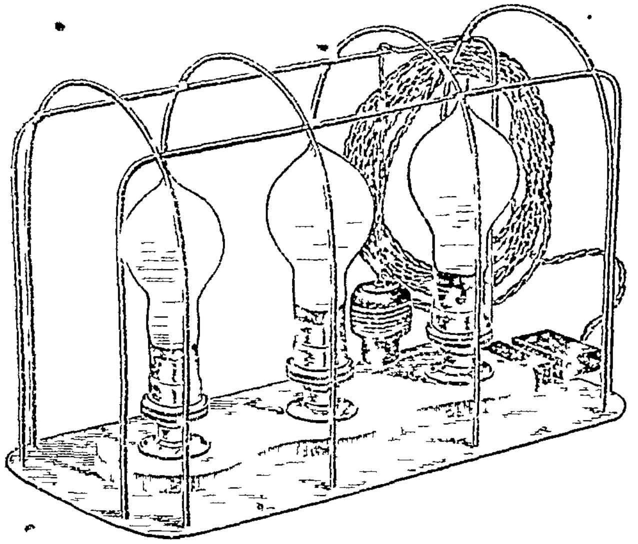
One word more as to the method of operating in these recent cases. It is of the utmost importance that the middle-ear structures should be respected, and for this reason I again repeat that Schwartze's method should be adopted, associated, if necessary, with the removal of any softened bone which may be found in the lower part of the process. If these rules be adhered to we commonly find that the discharge from the ear ceases, the membrane heals, and almost perfect hearing results.

Edinburgh.

A SIMPLE FORM OF ELECTRICAL LIGHT AND HEAT BATH, WITH EIGHT CASES OF OSTEO-ARTHRITIS TREATED BY IT.

BY F. C. EVE, M.B. CANTAB., M.R.C.P.,
HOUSE PHYSICIAN AT THE ROYAL INFIRMARY, HULL; LATE HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL.

THE apparatus[1] consists of three 32-candle power lamps fixed on an aluminium base and protected by a wire cage from contact with the skin of the patient or with the blankets forming the walls of the chamber. A piece of flexible wire connects the apparatus with the socket of any domestic lamp-holder, the lamp having been first removed. The amount of current consumed by the apparatus is not sufficient to damage the domestic installation or to blow fuses, and costs about twopence per hour. The apparatus may be used to heat up a single limb or the whole body and it has been employed in eight cases of chronic joint disease with the result that mobility has always been markedly increased and pain has been almost always entirely relieved.



The electrothermogen ready for use. The adapter at the end of the coil of flexible wire is merely substituted for an ordinary incandescent electric lamp in the bedroom or ward and the current then switched on.

The limb, the apparatus, and a thermometer are all placed together under a chamber formed of several blankets thrown over a cradle. The limb is covered with a single layer of lint to prevent any risk of scorching a particularly tender skin. This is gradually withdrawn in successive baths. The temperature of the chamber rises in from 15 to 30 minutes to from 200° to 250° F. The limb sweats copiously and a general perspiration is induced. As a rule the body temperature rises two or three degrees, especially when the whole body is treated. Frequently the limb acquires a transient mottled erythema. Even in the most obstinate cases pain practically always subsides by the end of the hour and generally it does not recur for several days. Constitutional treatment should be directed towards supporting the patient's strength during a course of baths, which may be repeated daily or on every second or third day.

It is maintained that practically the same benefit is derived from this small apparatus as from the more elaborate contrivances now in use, but these unfortunately are either very costly or can only be hired at a high rental. The temperature is not so high in the electrothermogen, but it is as much as the patient can endure for one hour.

At the end of a bath a stiff joint is much more supple and less tender, so that an excellent opportunity for massage is afforded. If it is desired to treat the whole body, after the fashion of a hot-air bath, such as is given in cases of renal disease, it is necessary to employ two pieces of apparatus to heat the larger chamber. The wicker chamber of the bath above referred to serves very well, but a very portable framework has also been designed, over which blankets are thrown.

So far the treatment has been applied to eight cases of rheumatoid arthritis—all very severe cases in which pain and deformity were prominent symptoms. The ages ranged between six years and 60 years, and the results as regards pain and stiffness have been very good, but in some of my cases a "sticking point" seems to be reached beyond which improvement does not proceed. They are in no sense selected cases.

CASE 1.—The patient was a man, aged 59 years, with a history of 18 months' illness. Advanced osteo-arthritis was present in all the limbs, with swelling, lipping of the cartilages, contractures, stiffness, and constant dull pain. The patient had several hot-air baths with relief from pain. He had enlargement of the epitrochlear, axillary, and inguinal glands, especially of the former.

CASE 2.—The age of the patient was 21 years. There had been chronic arthritis in many joints for six months. One of the knees was much enlarged and very painful. The thyroid gland had been enlarged for three months. The pain remained unrelieved after undergoing seven well known methods of treatment extending over three months, but complete relief (persisting until discharge from treatment) was brought about by a few baths.

CASE 3.—The patient was a boy, aged six and a half years. He was a very pale, fragile boy, bearing a most striking resemblance to the picture in Clifford Allbutt's work illustrating rheumatoid arthritis in the child. For one and a half years he had had marked swelling in, and immobility of, almost every joint, associated with anæmia and enlargement of the spleen and of the axillary and inguinal glands. This condition had steadily advanced, leading to wasting of the muscles and contracture of the legs. He was given nine baths of half an hour at 180° F. He seemed to be able to tolerate no higher temperature and he was taken out directly his own temperature reached 100°. There was a decided increase in mobility of the joints, the knee being extensible through 50 additional degrees. But the child seemed to be too fragile for the treatment, so it was discontinued and the ground which had been gained was subsequently more than lost.

CASE 4.—The patient, a man, aged 37 years, gave a history of very severe arthritis affecting every joint, including the spine, the jaw, and the ribs, of 18 months' duration. He had had gonorrhœa two and a half years before any joint trouble appeared. On admission he was anæmic, the muscles were wasted, costal respiration was impossible, and movement of the jaw and neck was very limited. There was also a large amount of albumin in the urine with no sign of nephritis except œdema of the legs. He has now had over 40 baths, of from 170° to 250° F., lasting from one to two hours. The body-temperature rose regularly to from 100° to 102° during the bath, so that his temperature chart resembled that of tertian ague. His general condition improved very much after a few baths which he took with considerable relish. The mobility of the joints also improved a great deal up to a certain pitch and then it ceased. This improvement made him less helpless and more comfortable. He derived benefit also from massage applied after many of the later baths The albuminuria persisted. Dr. C. R. Box (whom I have to thank for permission to publish those facts which bear on the bath treatment of this case) tells me that there is no further improvement and that he relapses when treatment is discontinued.

CASE 5.—The patient, a female, aged 22 years, had had for six years pain and swelling in all the large joints in turn, but she now complained only of swelling and stiffness and constant pain in the small joints of the hands and in the right shoulder. Her illness had been of several months' duration. She had had for several months excellent outpatient treatment, but without benefit. A few radiant heat baths produced marked improvement in the mobility and lessened the pain. She has had now six weeks of bath treatment on alternate days (one hour at from 200° to 250° F.) and has had only three attacks of pain. Both epitrochlear glands, however, are still enlarged.

---

[1] This apparatus can now be obtained of the Boardman Electrical Patents Company, 10, Union court, Old Broad-street, E.C., price £3 It is supplied to medical men only. It is proposed to call it the "Electrothermogen."

CASE 6.—The patient was a querulous old woman, suffering from advanced rheumatoid arthritis, who after having two baths professed that the pain was much relieved. It had yielded to no other treatment.

CASE 7.—This was a very interesting case of what was to all appearances rheumatoid arthritis in the right hand and shoulder, following three weeks after being run over across the right chest and right forearm. The injury caused unconsciousness (15 minutes), fracture of the second and third costal cartilages, and paræsthesia in the middle and index fingers. It is now four months since the accident and there are marked stiffness and dry swelling and frequent pain in the joints of the right hand and in the right shoulder. There are also coarse creaking in the right shoulder and slight creaking in the knees. The x rays show no bony changes and there is no glandular enlargement. There is no glossy skin or other sign of trophic disturbance, except slight roughening of the upper half of the nails. Muscular wasting is present, with myotatic irritability. If this be a case of osteo-arthritis, as would at once be assumed in the absence of the history of nerve injury, it becomes the strongest piece of evidence which I have read of in favour of the neuropathic origin of osteo-arthritis. Under the radiant heat treatment the pain and mobility rapidly improved, but the "sticking-point" was soon reached and progress is now (after six weeks' treatment) very slow.

CASE 8.—In this case of pain, swelling, and stiffness of the small joints of both hands the patient is still under treatment. 13 baths have banished the severe pain and have vastly improved the mobility and usefulness of the hands. Only the hands and arms were treated, but a profuse general perspiration was always induced. Every other treatment had been tried without success and the Dowsing whole-body bath had proved too exhausting.

So far the treatment by this simple apparatus has only been applied to these eight cases of advanced and painful joint disease and the results show that in such cases it will succeed in relieving pain and stiffness when drugs fail, but that, like all other measures, it can in no sense cure this obstinate complaint. More favourable results would doubtless follow in gonorrhœal arthritis and in sprains where rapid recovery was important. My impression is that the light is beneficial as well as the heat, and one reason for this opinion is the transparency of human flesh and bone to these rays. This can be readily demonstrated by grasping an electric lamp with both hands in a dark room. I fancy, too, that *dry* blankets are helpful in raising the temperature of the chamber, and that they do so by condensing the vapour arising from the perspiration of the patient and thereby liberating the latent heat of this vapour. This effect can be shown experimentally by placing a clinical thermometer in the mouth surrounded by a few layers of dry flannel. The mercury will rise many degrees—e.g., 15°—above the real temperature of the patient, and this device may possibly be known to the professional malingerer.

I have not yet been able to use the apparatus for inducing perspiration in renal cases, but it would doubtless be more efficient, less troublesome, and less dangerous than the ordinary spirit-lamp arrangement, provided that an electrical supply were present in the ward or house. Nurses tell me that it is much less trouble.

The advantages claimed for this little apparatus are:—1. Small initial cost and trivial running cost. 2. Extreme portability and lightness. It is made of aluminium and will stow in a small handbag. 3. No smell. No risk from fire, which cannot be said of the ordinary bath used in cases of renal disease. 4. Temperature of the air raised to from 200° to 250° F.—a good deal higher than in an ordinary bath just referred to. 5. The current can be taken from the domestic electric light by taking out a lamp and replacing it by an adapter in two seconds. The amount of current used will not blow even a weak fuse. 6. Intense light as well as heat is produced, and the former can be proved to penetrate human flesh and bone and is probably of considerable sudorific and therapeutic power. 7. The one apparatus can be used indifferently for any part of the body, it being only necessary to arrange a cradle of suitable size. 8. The patient is treated in his own bedroom or ward without subsequent exposure to risk of chill.

In concluding, I have to thank Dr. Hector Mackenzie very sincerely for suggesting to me the problem of reducing the hot-air bath to its simplest terms, and for his subsequent kindness and help in placing his cases at St. Thomas's Hospital at my disposal. I must also thank Dr. G. F. Elliott, Dr. Frank Nicholson, and Dr. E. O. Daly for allowing me to publish their cases at the Hull Royal Infirmary.

ST. GEORGE'S HOSPITAL.

THREE CASES OF FRACTURE-DISLOCATION OF THE SPINE TREATED BY LAMINECTOMY.

(Under the care of Mr. HERBERT W. ALLINGHAM.)

THE operation of laminectomy for fracture-dislocation of the spine must necessarily fail to relieve in a large proportion of cases, for the cord must be pressed on by the displaced bone to an extent sufficient to prevent the passage of nervous impulses, and yet the pressure must not have been sufficient to tear through the cord. Yet laminectomy is always justifiable in fracture-dislocation of the spinal column when paralysis of the body below the lesion is present. It is but rarely necessary to lay open the dura mater in these cases, though it adds but little to the danger of the operation if asepsis is preserved. For the notes of the cases we are indebted to Mr. P. Lockhart Mummery, house surgeon.

CASE 1.—A man, aged about 45 years, fell down an area and was admitted into the Chelsea Infirmary on Dec. 24th, 1900. He was quite conscious on admission and on examination it was found that he was completely paralysed below the shoulder girdle and that there was complete anæsthesia below that point; he could move his arms but could not extend his wrist or fingers; breathing was entirely diaphragmatic. The knee-jerks were absent; the plantar reflexes were present. No deformity of the cervical spine could be felt, but a good deal of bruising subsequently developed at the base of the neck behind.

On Jan. 9th, 1901, he was transferred to St. George's Hospital. As he was evidently suffering from injury to the spinal cord at a level somewhere between the fifth and sixth cervical vertebræ and as no improvement in his symptoms had occurred since the accident Mr. Allingham decided to perform laminectomy.

The operation was done on Jan. 11th. The patient was placed on his face on the operating-table with his head over the end and supported by an assistant; chloroform was administered. Mr. Allingham made a median incision and cut away the fourth, fifth, sixth, and seventh cervical spines (the operation was rendered difficult by the fatness of the patient's neck and the consequent depth of the wound). He then cut through the laminæ with Hoffman's bone forceps and exposed the dura mater. The fifth vertebra was found to be dislocated forwards and its laminæ were pressing on the cord posteriorly; the laminæ were therefore cut away and the cord was freed. The dura mater was then opened; the cord itself looked normal. A large drainage-tube was inserted and the wound was sewn up. The patient was then placed on a water-bed and his head and neck were steadied with sand-bags. 24 hours after the operation his abdomen became much distended and his breathing embarrassed from the pressure on his diaphragm. He also vomited several times. A long rectal tube was passed and a large amount of flatus was expressed from the abdomen through it by manual pressure, the abdomen being compressed only during expiration so as not to interfere with respiration. In this way the distension was rapidly relieved and after an injection of morphia he went to sleep for several hours and was much better next morning. On Jan. 15th the paralysis of the arms had partly improved and sensation had returned above the umbilicus; there was also some sensation over the front of both thighs. The wound was dressed and the tube was removed. A good deal of cerebro-spinal fluid had escaped. On the 17th his temperature at night rose to 103° F. and there was evidence of cystitis; his bladder was accordingly washed out twice daily and salol was administered by the mouth. On the 18th his breathing was difficult and there were signs of bronchitis in both lungs. He was accordingly turned over on to his left side and subsequently was always kept in that position, so as to leave his right lung free from secretion if possible, as he could not cough up his secretion at all. His temperature rose to 102° and varied between that and 103° till the 20th, when it dropped to normal. On the 20th diarrhœa set in which proved to be intractable. All beef-tea and fluid-diet were stopped and fluids were reduced to a minimum; astringents and opium, &c., were administered and everything that could be thought of was tried, but the diarrhœa continued and after lasting for some time proved fatal on Jan. 26th. On the 22nd he was able to move his legs very slightly and complained of twinges of pain in them. There was further slight improvement in the paralysis till death.

Necropsy.—At the post-mortem examination the cord was found to be normal except for some slight softening at the level of the injury. The intestines appeared to be quite normal and no ulceration or other lesion could be found to account for the diarrhœa. On examining the bladder there was evidence of some old cystitis chiefly confined to the neighbourhood of the trigone and a large abscess containing pus was found in his prostate. This abscess did not communicate with either the bladder or the rectum, though both were very carefully examined for such a communication. His other organs were normal except for some congestion of the lungs.

CASE 2.—A man, aged 30 years, was crushed in a lift accident on April 18th. On admission into St. George's Hospital there was marked irregularity of the eleventh dorsal spine with absolute paralysis and loss of sensation below that level. On the 19th, 24 hours after the accident, sensation had returned except in the soles of the feet. On the 20th, as no improvement had taken place in the paralysis, it was thought advisable not to wait any longer. Mr. Allingham performed laminectomy, gas and ether being administered. He made a median incision and removed the spines of the tenth, eleventh, and twelfth dorsal vertebræ and cut through the laminæ. On exposing the dura mater it was found to be torn and there was a large clot beneath it pressing upon the cord; this was removed, a drainage-tube was inserted, and the wound was sewn up. The patient rallied well from the operation. On the 22nd the drainage-tube was removed and the wound was found to be healing. Gradual improvement took place and the wound healed rapidly. On June 8th he had regained complete control over his sphincters, which had been previously absent, and could move his legs slightly. On the 27th all the paralysis had disappeared and he could walk with assistance, and on August 8th he was discharged from the hospital quite convalescent and shortly afterwards was able to resume his duties.

CASE 3.—A man, aged 56 years, was admitted into St. George's Hospital, having fallen down a flight of stairs. On admission there was complete paralysis of the lower limbs, abdomen, and thorax, respiration being carried on by the diaphragm alone; both hands and forearms were paralysed; the deltoids, however, were not paralysed. There was complete loss of sensation below the second rib. Priapism was present and there were no knee-jerks; the plantar reflex was well marked. No deformity of the spine could be felt. A diagnosis was made of fracture of the cervical vertebræ and pressure on the cord at about the level of the sixth cervical vertebra, and immediate laminectomy was decided on.

Anæsthesia was commenced with gas and ether and continued with chloroform, the patient being placed face down on the table. Mr. Allingham made a median incision from the fifth cervical to the second thoracic spine; the fifth cervical vertebra was found to be dislocated and pressing on the cord; the laminæ and spines of this and the sixth cervical vertebra were cut away and the dura mater was opened; the cord itself was much injected. The wound was closed and a drain was put in. The body temperature previously to operation was 101·5° F. About five hours afterwards it had risen to 108°. Cold sponging was tried with a view to diminish it but without effect, and in about an hour the man died, the temperature rising after death to 110°.

Necropsy.—At the post-mortem examination the second rib on the left side was found to be fractured as were the fifth and sixth cervical vertebræ. The cord in this region was quite free from pressure but was much softened. There were well-marked atheroma of the blood-vessels and a rather flabby heart. The lungs were much engorged with blood.

Remarks by Mr. MUMMERY.—In Case 1 the patient was a very stout and alcoholic individual and consequently was not at all a good subject to recover from such a serious injury. In spite of this, however, he lived for 33 days and at the time of his death, although only 15 days after the operation, there were already marked signs of improvement in the paralysis and anæsthesia. The diarrhœa, which undoubtedly was the cause of his death, appears to have been due to some atonic condition of the intestines, as no lesion could be found to account for it. Whether the abscess in his prostate was secondary to the cystitis or *vice versâ* there was nothing to show; it did not, however, appear to have resulted from the careless use of a catheter. The case is of some interest as it shows that the spinal cord is capable of recovering, to some extent at any rate, after having been subjected to pressure for a considerable time, in this case for over a fortnight.

Case 2 is chiefly of interest in showing what a long period of time is often necessary for the complete recovery of a damaged cord. The operation was performed on April 20th and recovery was not complete until June 27th.

Case 3 is a curious one, as the temperature rose to such a remarkable height and very well marked local softening of the cord was present though the patient only lived a few hours after the accident. The operation did not appear to hasten death in any way, as the temperature had commenced to rise already, and rose steadily until at 108° it proved fatal. It seems possible that the high temperature and softening were the result of a very acute myelitis.

These cases show the value of early operation in all cases of fracture-dislocation of the spine where there are symptoms of cord lesion. The operation itself is not a dangerous one and the patients seem to get over it very well. In the majority of the cases some lesion which can readily be dealt with is found, and the cord is able to be relieved of pressure by simply removing the laminæ of the affected vertebræ and those of the vertebræ above and below. A large incision greatly facilitates the operation. Laminectomy stands in the same relation to compression of the spinal cord as trephining does to compression of the brain, and the teaching of modern surgery is to trephine all cases of compression of the brain as soon as it can be localised. The same law seems to apply to compression of the spinal cord, and in the latter case there is the additional advantage that the localisation is generally quite easy. Even if nothing is found on exploring the dura mater little harm has been done and more patients will be saved by early operation than by leaving them alone. With regard to anæsthetics, there does not seem to be any serious contra-indication to chloroform, patients usually taking it well; ether is contra-indicated, as it is liable to cause some congestion of the bronchi, and the patient in a case of cervical injury is unable to cough up any secretions that may collect in his lungs.

CREWKERNE HOSPITAL.

A CASE OF COMPOUND FRACTURE OF THE PATELLA AND TRAUMATIC DISLOCATION OF THE KNEE.

(Under the care of Dr. J. H. LAMB.)

COMPOUND fractures and wounds of joints demonstrate as clearly as any other department of surgery the great benefit of antiseptic treatment. At one time a wound of the knee such as occurred in the following case would certainly have been followed by prolonged suppuration with destruction of the joint, even if pyæmia or septicæmia had not occurred, while with antiseptic treatment a moveable joint was obtained. The circumferential wiring of a fractured patella is certainly the simplest method and gives excellent results.

A man, aged 60 years, was admitted to the Crewkerne Hospital on June 22nd, 1900. The same afternoon, whilst at work with a scythe, he slipped and fell on it. When first seen the wound was wrapped up in old dirty cloths, and on these being removed the cut edges of the patella could be distinctly seen. Ether was administered and the wound was thoroughly examined. The scythe had cut the patella in two and opened into the synovial sac of the joint; the internal lateral ligament was divided for about half of its extent and the external lateral ligament was completely severed, so that only a small part of the internal ligament and the posterior ligament was left uninjured. The whole wound was filled with blood-clot. This was washed out with corrosive sublimate (1 in 2000) and the articular surfaces of the joint were found to be uninjured. The synovial membrane were first stitched and the joint was again well washed out with the lotion. The lateral ligaments were next sutured with a fine cat-gut suture and the rest of the wound was again douched with the lotion. No bone drills being obtainable the divided edges of the patella were drawn together by wire stitches passed from below upwards through the ligamentum patellæ and the tendon of the quadriceps extensor, so that the wire passed completely round the patella The wound was again washed and the skin and superficial fascia were drawn together by silkworm-gut. A dry boric dressing was applied. By the next day the dressings were soaked through by a bloody discharge. The temperature was 100° F. but the pulse was only 76, and as the dressings had dried the wound was left alone. Up to July 1st the temperature ranged from 99° to 101·4° (on June 25th), but as there was no corresponding increase in the pulse-rate the wound was left alone till July 3rd, when it was dressed and found to have healed by first intention. The stitches were removed and a dry boric dressing was applied. The patella was in good position and no movement at the cut surface could be obtained. On the 4th the wound was again dressed, the leg was put up in plaster-of-Paris, and the patient was discharged from the hospital. In three weeks he was re-admitted to the hospital, when the plaster was removed and the wire stitches were taken out. There was a slight amount of movement of the joint. By the end of August he could walk very well with a flexible knee-joint. On Sept. 16th he returned to work with a good moveable knee-joint.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Intestinal Intoxication due to Appendicitis.—Pharyngeal Pouch of Large Size Removed by Operation.

A MEETING of this society was held on May 14th, Dr. F. W. PAVY, the President, being in the chair.

Dr. SIDNEY MARTIN communicated a paper on a case of Intestinal Intoxication due to Appendicitis. The patient, a man, aged 50 years, under the care of Dr. C. D. B. Hale, was brought to Dr. Martin with symptoms pointing to intestinal intoxication. In the summer of 1899, on the voyage home from Norway, he was sea-sick and he suffered somewhat from looseness of the bowels. There was no indigestion, but there was gradual loss of appetite. The motions, although not very frequent, were never solid, and they became more and more offensive. There was never any slime or blood with the motions. Eight weeks after the illness commenced the most marked symptoms were pallor with cachexia, great emaciation, and flabby muscles. There were no signs of organic disease in any part of the body. The temperature was irregular. The intestinal evacuations were not very numerous, from one to three daily, but they were always liquid and extremely offensive. Several large lumps proved to be pieces of apricot which, on inquiry, were found to have been eaten eight weeks previously. Repeated examination failed to discover any cause of the intestinal decomposition. The treatment adopted at this stage was flushing the colon with solutions of boric acid. The wasting continued, the patient losing 11 pounds in 15 days, so that his condition had rapidly become desperate. He was now extremely weak and greatly emaciated. The deep inguinal glands of the right side were enlarged. At one examination of the abdomen a mass was felt in the right loin and it was decided to explore the abdomen. At the operation (December, 1899) it was found that the mass felt in the right loin was the kidney, which had become readily palpable owing to the great emaciation. The cæcum was thickened and the appendix was enlarged, both being elongated and thickened, while there were some calcareous glands between the ileum and the cæcum. The appendix, the two calcareous glands, and one other enlarged gland were removed An examination of the appendix showed enormous thickening of the coats. The contents were extremely fœtid, like the motions, and consisted of one or two fæcal concretions, as well as much liquid matter. Two small erosions were seen in the mucous membrane. The diseased appendix was considered as the origin of the patient's condition. After the operation the patient was in an extremely weakened condition and there were occasional slight rises of temperature due to suppuration round the stitches of the wound. Recovery, however, although gradual, ultimately became certain. In June, 1900, a small quantity of albumin was discovered in the urine with some casts, the specific gravity being 1017. At the end of July, the bowels were only occasionally loose and possessed no fœtor. The renal signs gradually disappeared, and 10 months after the operation the patient was completely restored to health. Commenting on the case, Dr. Martin remarked that disease of the appendix causing acute or subacute disease was usually associated with definite physical signs, but in the case which he had recorded there was severe illness due to chronic disease of the appendix in which the main symptom was the decomposition of the intestinal contents causing a profound general intoxication. In adults prolonged intestinal decomposition was usually associated with obstruction in one or other part of the colon or with chronic dysentery, and in this case these were regarded before the operation as the most likely causes, but the history of these was wanting in the case. The long retention (two months) in the intestinal tract of comparatively large pieces of apricot in a case in which there was continuous looseness of the bowels was an unusual circumstance worthy of note. The superficial lymphatic glands in the inguinal region and other parts were easily felt and on the right side, near Poupart's ligament, one deep inguinal gland more particularly was distinctly enlarged. This enlargement rapidly disappeared after the operation and it might probably be considered as part of the intoxication process There was in this case no bacterial infection as far as could be discovered; the walls of the thickened appendix showed no bacteria and there were none in the microscopic sections of the lymphatic gland which was removed from the abdomen —Mr. RICKMAN J. GODLEE, referring to the surgical aspect of the case, remarked that the abdominal pain was referred to a point distant from the real position of the appendix. Enlargement of the inguinal glands in association with appendicitis, such as occurred here, was a new fact in his experience.—Mr CHARTERS SYMONDS questioned whether the interpretation put upon the case by Dr. Martin was the correct one. Would not the facts be more correctly explained on the supposition that the patient was suffering from ulcerative colitis in which the appendix participated? The operation did not seem indispensable to the recovery which was perhaps the natural course of the disease. The four symptoms—looseness of the bowels, odour of the fæces, irregular temperature, and profound emaciation—formed a clinical picture of ulcerative colitis, and he was reminded of a patient suffering from that disease who had recovered from five successive attacks, in each of which he had presented all these four symptoms. On the other hand, it was doubtful if any form of appendicitis gave rise to a set of symptoms like those in Dr. Martin's case. Acute appendicitis [illegible] generalised sepsis, and he refer [illegible] over, it appeared to him [illegible] free communication with the cæcum could in any circumstances produce a series of symptoms such as those which had been described —Mr. JOHN H. MORGAN had known the patient in early life; he had been a great athlete, and had certainly not had tuberculous or other disease in youth. He was staying with Mr. Morgan shortly before his illness and had had no looseness of the bowels prior to Nov. 7th, 1899. The question as to what was the cause of the enlargement of the glands was an interesting one Probably this was due to the collection of decomposing matter in the appendix, which at the same time caused the general infection There were several very unusual features about the case.—

Dr. **C. D. B. Hale** remarked that the condition of the appendix was so extremely fœtid that it had to be immediately removed from the room.—Dr. **Martin**, in reply, remarked that if Mr. Symonds had seen the patient before and after the operation he would have had no doubt about causal relationship of the latter with the recovery. There was not quite a free communication between the appendix and the cæcum. He regarded the appendix as a sort of test-tube which inoculated the rest of the large intestine. The smell was quite peculiar and it was identical in the contents of the appendix and in those of the cæcum. This case was not like any case of ulcerative colitis which he (Dr. Martin) had ever seen.

Mr. **Rickman J. Godlee** and Mr. **T. R. H. Bucknall** communicated a paper entitled "A Pharyngeal Pouch of Large Size Removed by Operation" which is published *in extenso* at p. 1387 of our present issue.—Sir **Felix Semon** complimented the authors and remarked that perhaps the most important part of the paper was that referring to the unity of the several cystic and other malformations in the front of the neck, a fact which was first recognised by Kostanecki in 1890. He had met with two cases of this kind. One was that of a young man who came to him with a swelling at the side of the neck between the hyoid bone and the lower border of the cricoid cartilage, an egg-shaped moveable tumour which gave distinct fluctuation and which he regarded therefore as an ordinary cyst. He evacuated some material resembling ordinary pus, but the cyst filled again in a week. Again it was incised, caseous débris being evacuated, and again it refilled. Every conceivable method of treatment was tried, but the sinus never healed satisfactorily. The other case was that of an uncomplicated fistula with slight mucous discharge at the side of the neck which ended blindly close to the tonsil. Taught by past experience he took steps for the dissection and removal of the entire tract and the patient recovered. These cases should never be probed or interfered with unless they were prepared to deal thoroughly with the case in order to extirpate the disease.—Mr. **Arthur Barker** referred to a case which had many features in common with that related by Mr. Godlee, but it was on the other side of the neck. It differed, however. He regarded it at first as a dermoid cyst, because, in the first place, the right auricle was badly developed, and, secondly, there was a tuft of hair in a depression below the neck, and the tumour varied in size from time to time. Thirdly, it had a soft, doughy feeling. The patient felt very ill at the time, possibly indicating auto-infection. This tumour he (Mr. Barker) removed. In front of the tumour was the sterno-mastoid and behind it were the carotid vessels, to which it was adherent by inflammatory adhesions. The tumour could be traced upwards to close beneath the tonsil from near the episternal notch below. There was no doubt a narrow opening into the pharynx. The chief point of interest was the diagnosis of this case from a dermoid cyst. After removal the patient's general health greatly improved. —Mr. **Godlee**, in reply, expressed surprise that Sir Felix Semon had not met with more of these cases, because he (Mr. Godlee) regarded them as fairly common in surgical practice. He had seen a good many of these fistulæ which opened mostly at the top of the sternum beside the sterno-mastoid. In the case under discussion he began the operation under the idea that it was of œsophageal origin, partly because of the history of injury.

MEDICAL SOCIETY OF LONDON.

A meeting of this society was held on May 13th, Mr. **John H. Morgan**, the President, being in the chair. The proceedings will be reported at length next week.

The annual general meeting of the society was held before the ordinary meeting, and as the result of the ballot the following gentlemen, as nominated by the council, were elected to serve in the respective offices during the ensuing year:—President: Dr. William Allchin. Vice-Presidents: Dr. Isambard Owen, Sir W. Mitchell Banks, Dr. Thomas T. Whipham, and Mr. Charles A. Ballance. Treasurer: Mr. David H. Goodsall. Librarian: Dr. Sidney Martin. Honorary secretaries: Dr. Arthur F. Voelcker and Mr. Jonathan Hutchinson, jun. Honorary secretary for foreign correspondence: Dr. William Ewart. Council: Mr. Howard Barrett, Mr. J. Bland-Sutton, Dr. Henry A. Caley, Dr. James Calvert, Dr. J. Walter Carr, Dr. William R. Dakin, Mr. Frederic Durham, Dr. Robert A. Gibbons, Dr. Wilfred J. Hadley, Mr. Walter H. Jessop, Mr. John H. Morgan, Mr. C. W. Mansell Moullin, Dr. Frederick S. Palmer, Dr. Sidney P. Phillips, Dr. H. Campbell Pope, Mr. George R. Turner, Mr. Frederick C. Wallis, Mr. Herbert F. Waterhouse, Dr. Samuel West, and Mr. Edwin F. White.

CLINICAL SOCIETY OF LONDON.

Cancer of the Stomach with Unusual Vascular and Blood Conditions.—Perforating Gastric Ulcer causing Subdiaphragmatic Abscess bursting into the Lung.—Cases illustrating the Value of Laparotomy in Ascites.

A meeting of this society was held on May 10th, Sir **R. Douglas Powell**, Bart., the President, being in the chair.

Dr. **W. Pasteur** and Dr. **C. Price Jones** communicated a paper on a case of Cancer of the Stomach with Unusual Vascular and Blood Conditions. The patient, a metal chaser, aged 61 years, had suffered from gastric trouble for five years. On admission he was very weak and profoundly anæmic and was much emaciated. A tumour was felt near the umbilicus which moved with respiration. The symptoms pointed to cancer of the stomach. On the sixth day after admission the nose became dusky and two days later had acquired a deep purple colour with sharply defined margin which persisted till death. At the same time the toes of both feet became blue-black in colour and insensitive. No pulsation was perceptible in the posterior tibial and dorsal arteries. A few small bullæ containing clear sterile fluid formed on the toes of the right foot. An examination of the blood made on the same day showed red cells, 1,460,000, and white cells, 24,000. Analysis of the white cells gave: hyaline mononuclear cells, 44·59 per cent.; granular polynuclear cells, 54·35 per cent.; granular mononuclear cells, 1·02 per cent.; and numerous normoblasts, megaloblasts, megalocytes, microcytes, and poikilocytes. Death took place 12 days after admission. The necropsy revealed a cancerous growth infiltrating the wall of the stomach near the lesser curvature and invading the adjacent structures The right posterior tibial artery was patent and appeared healthy. The capillary stasis in the nose and feet was indistinguishable from the condition often met with in Raynaud's disease. The state of the blood, though resembling that of pernicious anæmia in several respects, differed from it in others, notably in the increased number of white cells and the preponderance of normoblasts over megaloblasts. Various observers had recorded states of the blood somewhat resembling that of pernicious anæmia in cases of malignant disease, but the results so far had not established the existence of any special diagnostic characters —The **President** remarked that the case was one of considerable interest as throwing some light on those cases, which were not uncommon, which were supposed to be pernicious anæmia but which turned out to be cancer and very often cancer of the stomach. He asked if the ears were involved in the capillary stasis.—Dr. **William Hunter** wished to remark on the importance of the distinctions between cancer and pernicious anæmia. He thought that the confusion of these two diseases was largely artificial. The resemblances between these diseases, the sallowness and pallor, were superficial, but the blood changes were absolutely distinctive Moreover, post mortem, pernicious anæmia was readily identified by the excess of iron in the liver. This did not occur in cancer. In Dr. Pasteur's case the amount of anæmia was exceptional and the leucocytosis only reached 28 per cent. In cancer the leucocytes often reached 70 or 80 per cent In pernicious anæmia it was quite unusual to find any excess of white corpuscles. He regarded the case before the society as quite exceptional. The association of these blood changes (which did not correspond with those of pernicious anæmia) with gastric cancer was, he believed, accidental.—Dr. **Batty Shaw** asked if there was any excess of urobilin in the urine. He referred to a case under his care of secondary anæmia which had lately developed numbness and tingling of both hands and signs of Raynaud's disease. He asked if the knee-jerks were altered.—Dr. **Pasteur**, in reply, regretted that the case was unavoidably imperfect in many respects. The ears and the hands were not involved in the capillary stasis. There were no obvious changes in the urine. The knee jerks were, he believed, normal.

Dr. **Norman Dalton** read a paper on a case of Perforating Gastric Ulcer causing a Subdiaphragmatic Abscess which burst through the diaphragm into the lung. The patient was a woman, aged 25 years, who was admitted into King's College Hospital on Feb. 20th, 1901. Her illness began on Feb. 12th with an aching pain below the cardiac area. On the 14th there was retching but no "vomiting" and no hæmatemesis. There was no pain on taking food. There was slight improvement for a day or two, but then the pain in the left side returned with great severity and was accompanied by great dyspnœa. On admission the temperature was 102 6° and all the signs of fluid at the left base were present. In particular the heart was displaced to the right. It was most noteworthy that although the dyspnœa was very severe the patient lay on the right side. 15 ounces of "clear" fluid were at once drawn from the left pleura. After this tapping tubular breathing was heard at the left base where previously no breath sounds had been audible. There was some relief after the tapping, but on the 22nd there was a severe rigor, and from that day until her death, on March 2nd, there were high remittent fever with several rigors and all the appearances of pyæmia. The physical signs, however, showed that there was no return of the fluid, because (1) the heart was now drawn over to the left side, and (2) a large area between the left nipple and the margin of the ribs as far back as the axilla gave, on percussion, a tympanitic note like that of the stomach. There were no breath sounds over the tympanitic area. It was thought that the lung had been unable to expand and consequently that the heart had come over to the left and the diaphragm and stomach had ascended. As a matter of fact, the tympanitic area was the cavity between the stomach and the diaphragm, which was due to the perforation of the gastric ulcer and the contents of which pushed up the heart and compressed the lung. While she was in the hospital there was no symptom whatever to draw attention to the stomach. Nourishment was taken freely and did not excite pain. Neither was there any cough or expectoration until the morning of March 2nd. The first sputum had a smell, remarkably like lactic acid. Later, however, it became gangrenous in odour and death occurred that night. At the necropsy an ulcer of about the size and shape of an almond was found in the anterior wall of the stomach close to the lesser curvature and about two inches from the cardia It had perforated, but the hole was now closed by the under surface of the liver. From this point, however, a short sinus between the liver and the stomach passed upwards and to the left and opened into a large cavity between the left half of the diaphragm, the liver, the stomach, and the spleen. The cavity was full of decomposing materials but was quite shut off by good adhesions from the general peritoneal cavity and there was no general peritonitis. Above this cavity there was a hole in the diaphragm which led into a large cavity in the lower lobe of the left lung, which was also filled with decomposing materials. The pleura was quite obliterated around the hole in the diaphragm, which would account for the fluid which was drawn off not being purulent. The lower part of the left pleura (from which the fluid had been withdrawn) was also now obliterated by adhesions. On reviewing the symptoms after the post-mortem examination it was evident that the case followed fairly well the usual course of events which occurred in cases of subphrenic abscess, and Dr. Dalton could only hope that this full report might be of use to others. He would emphasise the following points which have been mentioned by writers on this affection—viz., that these cases might occur without any symptoms to draw the attention to the stomach; that the fluid in the pleura, although close to a foul abscess, might be quite clear; and that the lung symptoms might obscure the real condition. He would also draw attention to the great pain in this case, especially when the affected side was pressed against. The absence of cough could not help the diagnosis, because pleurisy was really present and should have excited its own peculiar cough. The absence of sputum was not remarkable because there was no cough, but it was of extreme importance to note that the first sputum obtained smelt of sour milk, but that this smell was rapidly succeeded by an odour which was wholly gangrenous. As regards mistaking the tympanitic area for the percussion note produced by a stomach which was drawn upwards by non-expansion of the lung, he would plead that the left border of this tympanitic area was curved in a way that suggested the greater curvature of the stomach and that the heart was displaced to the left as well as upwards.—Dr. LEE DICKINSON regarded such cases of subdiaphragmatic abscess bursting into the lung as extremely rare. From the point of view of diagnosis this case was one of great interest.—Mr. LEONARD BIDWELL referred to a case which he had seen, of a man, aged 33 years, without any stomach symptoms. The case was regarded as one of empyema which had burst into the lung and he resected two ribs and opened an abscess in the lung. Shortly afterwards the patient ate some figs and the seeds were found in the dressings. Methylene blue was administered and this also was found in the dressings. Another rib was resected and the patient ultimately made a good recovery. Another case of subdiaphragmatic abscess under his care was that of a woman, aged 66 years. She had presented stomach symptoms, but her case was also diagnosed as one of empyema by means of the hypodermic needle. Several ribs were resected and offensive pus was evacuated, but she did not get well—every time she took solid food the temperature went up. An exploratory operation was performed and an opening through the diaphragm was discovered. Free drainage was established and a good recovery resulted.—Dr. FRANCIS HAWKINS (Reading) referred to the case of a woman, aged 27 years, who was admitted in an emaciated condition into the Royal Berkshire Hospital as a case of empyema in December, 1895. Four months previously she had been under treatment for gastric symptoms and 14 days previously had complained of pain in the side. 20 ounces of almost clear fluid were drawn off from the left pleura, but the patient did not improve. Ultimately there were physical signs which with the history suggested the possibility of a subphrenic abscess, but before any action could be taken the patient became suddenly worse and died. The necropsy revealed a subphrenic abscess containing about six ounces of pus between the left lobe of the liver, stomach, and spleen. On the posterior wall of the stomach was an ulcer which had perforated. The base of the left lung was adherent to the diaphragm and contained a small abscess communicating with that below the diaphragm. Dr Hawkins also referred to another case of subphrenic abscess which perforated into the pericardium. He agreed with a former speaker as to the latency of symptoms in some cases of gastric ulcer, mentioning two such instances in which perforation ultimately occurred. Both cases were operated on and recovered.—Dr. PASTEUR asked how Dr. Dalton explained the very quick change in the position of the apex-beat. It was too rapid to be due to adhesions. In his experience a tympanitic area over a previously dull area in any part of the chest was extremely suggestive of trouble from below.—Dr. C. R. BOX asked whether the ulcer was still active in Dr. Dalton's case or was the abscess due to the giving way of adhesions? What was the relation of the secondary ulcers to the first? were they of an infective nature?—Dr. DALTON replied that the ulcer was clearly an old one and surrounded by adhesions to the liver. After the perforation the stomach was shut off from the pleura by adhesions. He had thought that multiple ulcers indicated multiple embolism, not infection.

Mr. LEONARD BIDWELL read a paper on Some Cases illustrating the Value of Laparotomy in Ascites. He referred to three cases, in the first one of which the ascites had been due to cirrhosis of the liver; the liver and the omentum were stitched to the abdominal parietes after evacuating the fluid. The patient recovered and had no return of ascites; she remained well for nearly six months when she died suddenly from hæmatemesis brought on by alcoholic excess. In the second case, that of a child, aged nine years, the ascites had been preceded and it was accompanied by albuminuria and abdominal pain. There was also general anasarca. The lad had been tapped 10 times and the fluid reappeared very rapidly. He was now quite well but for a trace of albumin and had had no further ascites. In the third case, that also of a child, aged nine years, the ascites was due to cardiac disease and there was also general anasarca, the liver being greatly enlarged. In this case, too, there was no fresh development of ascites and the child was able to get about, but died from syncope shortly after returning home. The technique of the operation was described, and Mr. Bidwell expressed himself as rather opposed to the employment of drainage in the operation, since this made it very difficult to prevent septic peritonitis, a complication which in a patient with cirrhosis was almost certainly fatal. Several cases had been lost in this way, and he himself lost his first case about four years ago in a similar way. He referred to a series of cases of operation recently collected by Pachard and Lelanto. They had tabulated 22 cases, of which five died within 14 days and nine were cured; adding two more recent cases and his own five cases, the total of 29 recorded cases was attained; of these, eight died within 14 days of the operation, five other cases died within nine months, five did not improve, two improved, and 10 were cured. He thought that some selection should be made of the cases, the most suitable being those in which the liver was still enlarged. A small contracted liver was, in his opinion, a contra-indication to operation. He did not think that renal or cardiac disease was any contra-indication to operation.—The PRESIDENT suggested that it would be useful to classify these cases according as they were cardiac, hepatic, or, as in some of the author's successful cases, of a complicated nature. He congratulated Mr. Bidwell on his excellent results.—Dr. ALEXANDER MORISON remarked that it was possible to avoid laparotomy in a large proportion of these cases by adopting other procedures. His subsequent experience had confirmed his previous observations. In cardiac cases it was a question whether obliteration of the peritoneal cavity was an unmixed advantage. He referred to a case of cirrhotic ascites in a man who was ultimately cured by having the abdomen firmly strapped by a many-tailed bandage. A cardiac case treated similarly had also been cured. One of the most remarkable of his cases was that of a man who presented a cachexia suggestive of malignant disease who had made a complete recovery under the strapping method. Encouraged by these results he had recently applied the same treatment to cases of tuberculous peritonitis with promising results. The peritoneum might be regarded as part of the lymphatic system, and strapping expressed the fluid from the peritoneum into its proper channels. The principle of aspiration within the thorax was also brought into operation. Tapping and strapping were, he thought, much preferable to laparotomy and scrubbing the peritoneum —Dr. JOHN FAWCETT related an unsuccessful case of laparotomy for ascites. The patient was admitted to hospital in January last with some fluid in the abdomen which was attributed to cirrhosis After trying medicinal treatment he asked Mr. A. D. Fripp to perform laparotomy, with scraping and suture of the liver to the abdominal wall, and the patient died five days later. Previously he had been in favour of this treatment, but in future he would hesitate to recommend it.—Dr. DALTON referred to a case brought forward by him earlier in the session. He thought that the operation was practically unattended with risk, but there might be risks afterwards. There must be, for instance, a tendency to hæmatemesis after obliteration of the peritoneal cavity, or, as was suggested by Dr. H. D. Rolleston, there was a risk of poisoning by admixture of the portal blood with the general circulation. Neither of these risks presented themselves in his case, but the third, hernia of the abdominal wound, had proved fatal five years after the operation —Mr. BIDWELL, in reply, protested that undue weight was attached to the sequel in condemning laparotomy. If a patient died within a month of laparotomy it was set down to the operation, while if the patient died within a month after tapping it was attributed to the disease. He pointed out, too, that some adhesion took place after tapping, and after repeated tapping no doubt a certain number of adhesions were set up, thus assisting in bringing about a cure in the same way as laparotomy.

BRITISH GYNÆCOLOGICAL SOCIETY.

Adjourned Discussion on the Clinical and Pathological Consequences of Retroversion of the Uterus, their Preventive, Palliative, and Radical Treatment.—Posterior Vaginal Cœliotomy in Operations for Pelvic Disease.

A MEETING of this society was held on May 9th, Dr. J. A. MANSELL MOULLIN, the President, being in the chair.

Dr. HEYWOOD SMITH in continuing the discussion on Dr. H. Macnaughton-Jones's paper on the Clinical and Pathological Consequences of Retroversion of the Uterus, their Preventive, Palliative, and Radical Treatment, said that he thought that metritis and parametritis were more frequently the effect than the cause of misplacement. It was curious that five out of seven speakers had advocated the use of the stem. The dangers of the sound were sometimes exaggerated. Where there were no adhesions it might be used to replace the uterus, provided it were passed with gentleness, in the exact axis of the organ, and that reposition were assisted by the finger behind the uterus. He objected to the restriction of the word "radical" to cure by operation; by patience and quietness retroversion could be radically cured. Where poverty, however, rendered work essential operative treatment gave the best and quickest relief. He had been the first to perform a deliberate ventro-fixation in England.

Dr. J. J. MACAN questioned the propriety of employing the sound for purposes of reposition. Any uterus which could be safely thus replaced could be replaced bimanually by varying combinations of abdominal, vaginal, and rectal palpation. He asked Dr. W. Alexander to express an opinion upon the advisability of drawing the round ligaments out in their original direction when performing the Alexander operation; it was a point upon which considerable stress was laid in continental literature.

Dr. R. T. SMITH referred to the correctness of Hewitt's observations as to the association of neurotic conditions and still more of persistent vomiting with uterine displacement. In debilitated patients there were two conditions which conduced to retroflexions: (1) loss of the normal curvature of the spine, and (2) softness with consequent flexibility of the uterine tissue. Rest and removal of the primary cause were frequently attended by cure of the displacement. Prolapse of the ovaries sometimes resulted from enlargement and displacement of the uterus. If the uterine condition were treated the ovarian trouble disappeared. While approving of Alexander's operation, in cases demanding operative treatment he himself performed ventro-fixation.

Dr. H. SNOW asked Dr. Alexander whether he ever experienced any difficulty in detecting the round ligaments. Referring to the use of a support he said that in many cases it should be used rather with a view to rendering the vagina taut than to keeping the uterus in any position or at any particular angle.

Dr. F. A. PURCELL believed that undue prominence of the promontory of the sacrum contributed to retroflexion. In virgins it was not always possible to insert a pessary.

Dr. P. L. HEBERT said that in the majority of cases the sphincter formed the only obstacle; yet there were cases in which the vagina was cone-shaped, and in these, whether children had been borne or not, a pessary was with difficulty retained.

Dr. BENJAFIELD said that he had listened with great interest to the discussion; but it was frequently difficult to obtain admittance for such cases into hospital, yet the only practical cure for patients in a poor neighbourhood, such as that in which he practised, was operation. To advise the majority of patients to rest and to use douches was utterly impracticable.

Dr. R. H HODGSON said that frequent reference had been made to the condition of the bowel. What portion of the bowel had been referred to? He failed to see how retroflexion could be attributable to distension of the rectum.

Dr. ALEXANDER, in reply to questions addressed to him, said that he attached no importance to the direction in which the ligaments were drawn out. The secret of finding them was to cut down upon the external oblique, which was a distinct glistening structure, and then seek the extrusion of the external abdominal ring. Except where abnormalities existed the ligaments were always there but in about 1 per cent. of cases were too thin or too brittle to pull out. An apparently delicate ligament, however, on being pulled a little way out of the canal proved thick and strong. He did not operate upon very old people in whom the ligaments were specially liable to be delicate.

The PRESIDENT would classify backward displacements according to whether they were reducible or irreducible Etiologically, pathologically, clinically, and as regards treatment they would lend themselves readily to that division The division into retroversion and retroflexion was devoid of practical value. With regard to preventive treatment, the rules laid down by the various speakers as to the avoidance of strain at the menstrual period, examination and replacement of the womb after miscarriage or labour, and repair of the perineum or cervix if lacerated would meet with general acceptance. He doubted if the very temporary use of stems sanctioned by those favouring their employment could possibly be of permanent benefit, while the risks attending their use were admitted by all. The discussion had turned to a great extent upon the relative merits of ventro-fixation and Alexander's operation. The latter required skill and practice, while the former was devoid of any special difficulties and therefore evidence in its favour would be forthcoming from many quarters. The fundus was seldom bound down unless the uterine appendages were the seat of chronic inflammatory mischief and he regarded the position of the uterus as of secondary importance when the primary trouble had been removed.

Dr. MACNAUGHTON-JONES, in replying, said that each time he had referred to the bowel he had specified the overloaded rectum alone as a participating cause of the retroversion. He considered a stem pessary to be both unscientific and dangerous and the remarks of some of those who advocated its use had only tended to show that it was so. Lawson Tait was quite right in urging the comparatively rare necessity for the employment of the sound, either in diagnosis or as a repositor. As to a pessary, each should be adapted according to the anatomical peculiarities of the parts—the vagina and uterus. Dr. Macnaughton-Jones also dwelt on the importance of prophylaxis which prevented the necessity for either pessary or operation. He reminded the Fellows of the propositions which he had made with regard to the differentiation of those cases in which mobility and reducibility indicated either expectant or operative treatment, even when there were associated adnexal conditions. The cases demanding colpotomy without fixation were distinct. The vital points agitating gynæcologists with regard to operation, once any method was determined upon, were: (1) that method most suitable to the mobile and reducible uterus during and after the child-bearing period; (2) that appropriate to retroflexion with adnexal complications and adhesions; and (3) the bearing of the method on child-bearing and the consequences which followed to the parturient woman during labour. Abroad either Alexander's or the Alexander-Adams operation, with its various modifications, extra-peritoneal or intra-peritoneal, was performed by such well-known gynæcologists as Doléris, Cohn, Küstner, Kronig, Veit, Karl Peters, Delagénière, Bamberger, Stocker, Füth, Rumpf, Kocher, Doyen, and others; in America, by quite a number of surgeons, including Goldspohn, Edebohls, Mundé, Parker, Newman, and Kellog; while Lapthorne Smith of Montreal had performed a very large number of operations by this method. Taking the records of 1141 operations, the particulars of which Dr. Macnaughton-Jones quoted, there had been but two deaths. The plan of looping intra-peritoneally the round ligament, as advocated by Delagénière, Mann, Jacobs, and many others, or the fixing of the loop into that which tied off the ovary and tube if these be removed, had not been referred to. Up to the end of 1896 Martin had performed 400 vaginal fixations with only four deaths. Vineberg's operation of vaginal fixation of the broad and round ligaments had not in that operator's hands been followed by any death. Howard Kelly in his utero-suspension had not more than 1 per cent. of failures. Fixation of the broad and round ligaments to the parietal peritoneum was performed by some operators. Reviewing the statistics as published by a number of operators up to the present year it would appear that the choice lay mainly between three procedures, or the modifications of these, the Alexander-Adams operation, ventro-fixation, and Kelly's utero-suspension. It was clear that Alexander's operation could not be the simple procedure that some represented it from the modifications of it which were forced by necessity upon the most expert operators. Finally, the age of the patient, the complications of the displacement, and the operator's views with regard to the influence of the special operative interference on pregnancy and labour were the points that would determine the selection of any operation.

Dr. ALEXANDER read a paper on Posterior Vaginal Cœliotomy in operations for Pelvic Disease. During the preceding two years he had performed 94 posterior vaginal cœliotomies for various diseases of the pelvis, exclusive of such conditions as cancer, uterine fibroids, or other diseases where Douglas's pouch had been opened as a small part of a more extensive operation. As showing that [illegible] specially favoured operation of [illegible] rformed in all 1567 operations [illegible] these included 204 cœliotomies [illegible] een adopted. He had become [illegible] h the ease and shorter duration [illegible] the more rapid recovery of the patient. He lost but two cases, notwithstanding that he had operated for such conditions as hydrosalpinx, pelvic cellulitis, pyosalpinx (14 cases), hæmatocele, fibroid ovaries, peri-rectal abscess, ovarian cysts, dermoid cysts of the ovary, cystic ovaries, abscess of the ovary, &c. One of the deaths was due to pleuro-pneumonia. The second occurred in a case of abscess of the right ovary, in which, a great part of the organ being healthy, he was tempted to save it. In all similar previous cases he had removed the suppurating moveable structure. The ligature was the best method of treating the stump, but he generally employed forcipressure in this operation.

West London Medico-Chirurgical Society.—A meeting of this society was held on May 3rd, Dr. F. F. Schacht, the President, being in the chair.—The minutes of the last meeting were read and confirmed.—Dr. William Hunter read a paper on the Infective Nature and Septic Origin of Pernicious Anæmia, the paper being illustrated by a series of beautiful lantern slides. Dr. Hunter said that pernicious anæmia had hitherto been regarded as a mysterious disease and that it occurred without any discoverable cause. It had been taught that the chief factors accounting for its appearance were insufficient nutrition, unhealthy surroundings, hæmorrhages, and wasting discharges; that pernicious anæmia, in short, was a provisional shelter for a multitude of cases of possibly variable origin. The symptoms were formerly regarded as in nowise distinctive, but simply those arising from the anæmia, and, further, no morbid state or anatomical condition could be shown to be peculiar to this disease. Dr. Hunter had investigated this disease closely for some 15 years and had arrived at certain definite conclusions which were as follows. 1. As regards its nature the disease was not merely a specialised form of anæmia, but it was a definite and well characterised special infective disease localised to the mucosa of the alimentary canal, and one in which sepsis, both oral and gastric, appeared to play an essential and important part. It was accompanied by definite infective lesions of the mucosa, difficult to discover post mortem, but characterised when observed during life in the mucosa of the tongue as a glossitis. This was not the result of the anæmia and was very persistent, coming and going when once established in a most remarkable manner and independently of any obvious cause. This unhealthy condition of the mucosa was due in the first instance to long-standing oral and gastric sepsis the result of suppurating and necrosed teeth and this condition permitted a special infection to occur. 2. The typical mode of development was as follows: a history of oral, gastric, or intestinal trouble extending over many years without any anæmia, more or less suddenly followed by an anæmia out of all proportion to the severity of the symptoms and denoting the supervention of a new factor—viz., increased hæmolysis dependent upon a new and special infection of the alimentary canal. On inquiry it would generally be elicited that at or about the commencement of the anæmia the patient suffered from sores or lesions of the tongue. Experience lent no support to the view that ordinary anæmia-producing factors, if only severe enough, could give rise to this form of anæmia, and cases of the kind could be successfully excluded, not only during life, but still more easily after death, by the absence of the clinical features and anatomical changes which were found to characterise the disease. 3. Anæmia was only one of the symptoms of this disease and there were at least three other groups of symptoms—viz., hæmolytic, oral and gastric, and intestinal and toxic symptoms, these being caused by the infection which lay at the root of the disease, and being more or less pronounced in every case of pernicious anæmia. They had one factor in common—viz., their periodicity, variations in the severity of the symptoms being common from week to week corresponding with the activity of the infective process. By these symptoms the disease could be diagnosed with certainty during life and after death by the no less characteristic pigmentary changes in the liver. With regard to treatment strict antiseptic treatment both of the mouth and of the gastro-intestinal tract must be repeatedly carried out. Arsenic and iron supplemented in suitable cases by anti-streptococcic serum injections were found to be very useful.—The President had listened to the paper with great pleasure. It had been worked out with great care and was full of interesting points.—Dr. Herbert Snow thought that this was one of the most lucid papers that had ever been read before the society, but many of the conclusions arrived at were open to discussion. For instance, if the septic infection described were primarily due to carious teeth, how was it that while such a condition was so common pernicious anæmia was so rare? What was the pathogenic organism concerned? What were the tongue lesions like? What was the percentage of cases curable? A large number of cases supposed to be due to pernicious anæmia had been eventually proved to be due to tape-worm or to cancer, especially of the stomach.—Dr. Hunter, in reply, referred to his book and to other communications which he had written on this subject to answer many of the questions. He emphasised the point that sepsis alone was not the cause of the disease but the channel and basis by which the specific organism entered.—Dr. Stanley Melville read a description of 16 cases of Ulcerative Stomatitis occurring in his practice at the same time, all presenting more or less the same characteristic features—viz., local conditions, marked constitutional disturbance, moderately high fever, and subsequent severe prostration. The occurrence of several cases in the same house was suggestive of some epidemic origin. In most of the cases the gums were swollen and bleeding, small ulcers formed in the mouth and spread rapidly, vomiting with abdominal pain then set in, accompanied by great wasting and prostration. The submaxillary glands were swollen and tender and a petechial rash appeared on the arms. Treatment consisted of antiseptics, stimulants, ammonia, and bark. The nature of the infection was obscure. Microscopical examination revealed nothing. The milk-supply was suspected but was found not to be the vehicle of infection.—Dr. Charles Buttar read notes of a case of Pneumomycosis. The patient who had returned home from India was a stout woman, aged 52 years. She had suffered from palpitation and shortness of breath for some time and had the usual symptoms of emphysema of the lungs. In January she caught cold and was much troubled with shortness of breath and cough, the symptoms being worse at night. The tips of the fingers were slightly blue and the tongue was coated with thick fur. Little was to be heard in the lungs with the exception of a few moist sounds at the bases. Pains were felt in the back and in the chest. Expectoration was free, consisting of clear mucus, a little pus, and many black specks. There was slight œdema of the legs. The temperature was raised to between 98° and 100° F. Soon after the patient complained of sore-throat and the palate became red and inflamed and covered with aphthous patches, the sputum becoming very free. As she had been ill for four weeks the sputum was examined and was found to be free from tubercle bacilli but it contained enormous quantities of oidium albicans with some streptococci. The patient gradually improved and eventually recovered. There was little doubt that she was suffering from emphysema and bronchitis complicated by the presence of the oidium albicans which contributed to keeping up the trouble, but the question as to whether the presence of the fungus was primary or secondary was one which was open to doubt.

North of England Obstetrical and Gynæcological Society.—A meeting of this society was held at Manchester on April 19th, Dr. T. B. Grimsdale, the President, being in the chair.—Mr. Stanmore Bishop (Manchester) showed three specimens of Uterine Fibro-Myomata removed by abdominal hysterectomy. The first was from a multipara, aged 49 years, in whom there had been a rapid increase of the growth and symptoms during the recent few months The tumour was removed by Baer's operation. Although the uterus was divided at the level of the internal os no trace of the right Fallopian tube was seen in the specimen. It was apparently a fibroid occurring in an irregularly-developed uterus. The patient recovered well. The second specimen was from a married woman, aged 55 years. The symptoms had been present for 18 years and had rendered the patient a complete invalid. The tumour was very large, multiple, and adherent. One subserous pedunculated mass was calcified and a submucous growth had become necrotic, causing foul discharge. Total removal by Doyen's method was performed. Recovery was retarded by the formation of an abscess in the left iliac region. This was opened and the subsequent progress was satisfactory and recovery was complete. The third specimen was from a nulliparous married woman, aged 42 years. The growth was fibro cystic and it weighed 19 lb. It was removed by C. Martin's method of total hysterectomy and the patient did well.—Dr. Lloyd Roberts (Manchester) showed an Ovarian Tumour with Twisted Pedicle. The swelling had been noticed for 12 months. Three months before operation, and again six days before, there had been attacks of severe abdominal pain with vomiting. It was probable that the rotation occurred on these occasions and that hæmorrhage took place on the latter date. The cyst contained 100 ounces of dark chocolate-coloured fluid and the pedicle was twisted three times on itself, its vessels being thrombosed. The patient made a good recovery.—Dr. W. E. Fothergill (Manchester) exhibited: (1) A Uterine Cast from a case of Dysmenorrhœa having the shape of the uterine cavity, in which there was a small central space with no epithelial lining and the structure of which was composed of a delicate fibrous stroma with numerous round cells but no glands or vessels; (2) a Fibro-myoma of the Round Ligament from a patient who was suffering from peritonitis, the growth being found in the sac of an inguinal hernia and its pedicle being proved to be the left round ligament, the microscope showing it to be composed of fibro-myomatous tissue; and (3) Water-colour Drawing of Multiple Ulcers of the Inner Side of the Thigh and Vulva, the primary condition of which was one of kraurosis and the ulcers presenting epitheliomatous characters on microscopical examination.—Dr. J. W. Martin (Sheffield) showed a specimen of Double Pyosalpinx from a patient, aged 35 years, who had been married for seven years and was sterile. The history dated from a few months after marriage. There was no evidence or history of gonorrhœa. The tubes were removed and the patient had made a rapid recovery.—Dr. J. E. Garner (Preston) showed the following two specimens: 1. A Proliferous Ovarian Cyst removed from a patient who was between three and four months pregnant. There had been severe pain for about a fortnight before operation. The pain did not cease and abortion took place on the second day when the patient died from collapse. The fluid in the cyst was black. 2. A Fibro-sarcoma of the Ovary. The patient was a multipara, aged 35 years. The tumour had been noticed for about 15 months but it had rapidly increased during the last three months The tumour was easily removed. There was much ascites. The peritoneum was flushed with normal saline solution and closed without drainage. Recovery was uninterrupted.—Dr. E. T. Davies (Liverpool) showed: (1) Multiple Fibro-Myomata successfully removed from the lower uterine zone by morcellation per vaginam; and (2) Tuberculous Salpingitis associated with tuberculous peritonitis and ascites. The tubes were removed, the fluid was evacuated, and the peritoneum was flushed with normal saline solution. The wound was closed without drainage. The improvement was so far well marked.—Dr. W. J. Sinclair (Manchester) showed the specimen from a case of Tubal Pregnancy which had advanced to between five and six months without rupture of the tube. The sac and its contents were removed by abdominal section. The tumour was situated in front of and above the uterus and was very adherent and difficult to separate. A careful examination of the relations of the uterus and the ovaries and tubes with the sac proved that the latter was formed of the wall of the inner third of the Fallopian tube. There was a distinct interval between the sac and the uterus proper and the tube could be distinctly traced into and out of the cyst. There had been no rupture. The patient recovered.

Leeds and West Riding Medico-Chirurgical Society.—The last meeting of the session was held on May 3rd, Dr. Gordon Black, the President, being in the chair.—Dr. Christy Wilson (Doncaster) read a paper on four cases of Perforation of the Stomach and Duodenum successfully treated by operation.—Mr. H. Littlewood said that he had operated on 12 cases of acute perforated gastric ulcer and three cases of acute perforated duodenal ulcer. The gastric ulcers were all in women and the duodenal in men. Of the patients suffering from gastric ulcer only four had made complete recoveries; one lived for two or three months and died from an abscess in the lung and emphysema on the left side; another lived one week; and the remaining six died within a few hours of the operation, one of these dying as soon as the abdomen was opened. The cases of duodenal ulcer were all operated on after 36 hours from the time of perforation and all terminated fatally. Mr. Littlewood thought that the shorter the interval between the perforation and the operation the more likely were the cases to terminate successfully. In two of his successful cases he had not drained the peritoneum.—The President, Mr. F. Mayo, Mr. Basil Hall, and Mr. B. G. A. Moynihan also took part in the discussion.—Dr. J. Stewart read notes of five cases of Tubal Gestation. He held that it was not necessary to operate in every case of ruptured tube or tubal abortion, as four of his five cases recovered without operation. He preferred to advocate the plan of waiting and watching, and if any untoward event occurred to be prepared to operate at once, thus in a great many cases avoiding incisions in the abdominal wall, risks of ventral hernia, and interference with pelvic organs. In the first case the hæmorrhage was so slight and the length of time from the last period so short—viz., five weeks—that he looked upon it as a case of tubal abortion. Yet of the series it was the only case in which shock was a pronounced symptom, the patient nearly dying on two separate occasions from profound shock, an interval of seven days occurring between each attack. With the exception of shock all the classical signs were present in the five cases. In all there were amenorrhœa and a mass in the pelvis. In Cases 2, 3, 4, and 5 the amount of pelvic effusion was enormous. In Case 2 the effusion was looked upon as extra-peritoneal as there was well-marked stricture of the rectum, with tape-like motions. In four of the five cases a decidual membrane was present. The bleeding into the pelvis was very "quiet" in character (as it gave rise to few symptoms excepting the increasing size and discomfort of the pelvic mass) if Case 1 and the secondary hæmorrhage in Case 5 might be excepted. Cases 1, 3, 4, and 5 were regarded as intra-peritoneal, the latter being certainly so. The non-operative cases were kept in bed from six to 15 weeks, no trace of any pelvic storm taking place. The fifth case did well up to the seventeenth day after primary rupture, when secondary rupture took place and the patient almost succumbed. Dr. Stewart removed the tube under ether, leaving the ovary behind. The patient almost succumbed on the table but recovered as soon as flushing was commenced. Drainage was maintained for 24 hours. The silk ligature appeared through the drain track on the sixteenth day after the operation. The patient made an uneventful recovery. The tube, decidual membrane, and silk ligatures from the case were shown.—Cases and specimens were shown by Dr. S. Lodge, jun. (Bradford), Dr. T. Churton, Mr. Littlewood, Dr. J. B. Hellier, Mr. Moynihan, Mr. Constable Hayes, Mr. Lawford Knaggs, and Dr. E. F. Trevelyan.—The annual meeting of the society was held at the close of the ordinary meeting. The following officers were elected for the ensuing session:—President: Dr. A. G. Barrs. Vice-Presidents: Dr. W. L. Hunter (Pudsey) and Mr. C. Richardson. Committee: Mr. Edwin Lee (Dewsbury), Dr. F. A. Mouillot (Harrogate), Dr. H. J. Clarke (Doncaster), Mr. B. G. A. Moynihan, Mr. H. Secker Walker, Mr. C. J. Wright, Dr. F. W. Robinson (Huddersfield), Dr. Gordon Sharp, Dr. S. Long (York), Dr. Priestley Leech (Halifax), Dr. Gordon Black (Harrogate), Dr. W. A. Evans (Bradford), Mr. Edwin Roberts, Dr. A. H. Bampton (Ilkley), and Mr. Walter Thompson. Honorary secretaries: Dr. E. F. Trevelyan and Mr. Lawford Knaggs.

Glasgow Obstetrical and Gynæcological Society.—A meeting of this society was held on April 24th, Dr. John Edgar, Vice-President, being in the chair.—Dr. Andrew Richmond read notes of a case of Hydatidiform Mole. The patient, a young unmarried primipara, complained on March 5th, 1901, of sickness and vomiting of two weeks' duration. For the same time there was a blood-stained vaginal discharge, commencing with a menstrual period. The previous menses had been normal. The mammary areolæ were darkened, and the uterus was found to be enlarged. Early pregnancy was diagnosed. The vomiting did not yield to treatment, but it got worse, all food being rejected, while the pulse became rapid and feeble. By the 22nd the uterus had increased rapidly and out of all proportion to a normal pregnancy, and as it felt soft and boggy a diagnosis of hydatid mole was made. At this date the abdomen at the umbilicus measured 26 inches round, and three days later it was 28½ inches. The patient had to be fed by nutrient enemata, but as her condition became rapidly worse abortion was induced on the 29th in Paisley Infirmary. On the 31st septicæmia supervened and in spite of active treatment the patient died on April 7th. A post-mortem examination made the next day revealed a widespread septic peritonitis. The source of infection was found to be from a laceration or wound in the posterior vaginal fornix, leading to a semi-gangrenous area in the pouch of Douglas. The endometrium was also gangrenous, but the Fallopian tubes were not affected. As no violence was used and as the uterus expelled its contents naturally it remained unknown how the wound in the fornix originated. The strictest aseptic and antiseptic precautions had also been observed.—Dr. Edgar read notes of a case of Carcinoma Cervicis for which vaginal hysterectomy was performed. The case was brought forward to show the advantage of curettage and the application of formalin to the growth. This was done when the patient, aged 43 years, was first seen, as she was too ill to permit of a major operation. Three months later the patient was well and strong; she had gained 28 lb. in weight, was free from discharge, and she menstruated regularly and normally. A vaginal hysterectomy was then performed with success.—Dr. John H. Teacher gave a demonstration of Placental Structures at different months of Pregnancy, illustrated by lantern-slides and microscopic sections.—Dr. J. K. Kelly opened a discussion on the Causation, Nature, and Treatment of Retroversion of the Non-gravid Uterus. After referring to the normal position of the uterus and the factors which kept it there, he treated of the various causes of retroversion and classified them into mobile and fixed, primary and secondary, according as they were independent of, or merely an incident in, descent of the uterus. He regarded the wearing of a pessary as sufficient treatment in the majority of mobile retroversions. If the pessary failed he performed ventrofixation. He had abandoned vaginal fixation and Alexander Adams's operation. In cases of fixed retroversion it was sometimes possible to break down the adhesions under anæsthesia and to bring the uterus into a good position and to retain it there. Where this was impossible, and in other cases demanding operation, as for diseased appendages, he performed laparotomy, freed the uterus, removed the tubes and ovaries if desired, and finished by a ventrofixation to the anterior abdominal wall.—Further discussion was postponed till next meeting.

Bristol Medico-Chirurgical Society.—The eighth meeting of the session of this society was held in the medical library of University College, Bristol, on May 8th, Dr. D. S. Davies, the President, being in the chair.—The President proposed, and it was carried, "That a vote of congratulation be accorded to the honorary secretary (Mr. Paul Bush) on his receiving the honour of being made a Companion of the Distinguished Order of St. Michael and St. George for services rendered in connexion with the Boer War."—Dr. J. O. Symes showed Specimens of Blood with Malaria Organisms.—Dr. A. E. Aust Lawrence read a paper on Some of the Hæmorrhages of Pregnancy.—Dr. Barclay J. Baron reported a case of Paralysis of the Right Vocal Cord due to thoracic aneurysm and showed skiagrams taken by Mr. J. Taylor.—Dr. E. Markham Skerritt, Dr. P. W. Williams, Mr. W. H. Harsant, Mr. Paul Bush, Dr. F. H. Edgeworth, and Dr. K. Wills discussed the case.—Dr. J. Michell Clarke read a paper on the Treatment of Inveterate Cases of Sciatica.—Mr. H. F. Mole, Mr. Harsant, Dr. Edgeworth, Mr. C. E. S. Flemming, Dr. C. Elliott, Dr. J. Barclay Baron, Dr. G. Parker, and Mr. J. Hancocke Wathen remarked on the paper.—Dr. Parker reported a case of Congenital Obliteration of the Bile Ducts and showed specimens.

Glasgow Pathological and Clinical Society.—A meeting of this society was held on May 13th, Mr. Henry E. Clark, C.M.G., the President, being in the chair.—Dr. A. Ernest Maylard showed a case in which he had performed Colocolostomy for Stricture at the Upper End of the Sigmoid Flexure, and read notes of another case in which he had treated Multiple Tuberculous Strictures of the Small Intestine by Jejuno colostomy.—Dr. James Lawrie (Greenock) showed a case in which Excision of a Ruptured Traumatic Aneurysm of the Femoral Artery at the Apex of Scarpa's Triangle had been performed.—Dr. Henry Rutherfurd showed (for Dr. Newman): (1) A Resonator for Detecting Calculi in the Lower End of the Ureter; (2) Harris's Urine Segregator; and (3) Schlagintweit's Cystoscope.—Dr. Edward J. Primrose showed a specimen of: (1) Patent Pericardium; (2) Solitary Kidney with Single Ureter; and (3) Urinary Bladder with a Horizontal Septum—all from the same subject.—Fresh specimens:—Dr. Lawrie: Epithelioma of the Tongue.—Professor Muir: Sarcomata in the Dura Mater, Lungs, and Liver.

West Kent Medico-Chirurgical Society.—The seventh meeting of the forty-fifth session of this society was held at the Royal Kent Dispensary, Greenwich, on May 3rd.—Dr. Septimus Sunderland delivered his presidential address on Uterine Hæmorrhage: its Causes and Treatment.—After the address a most enjoyable smoking concert was provided by the generosity of the President. The following artists contributed to the amusement of the evening:—Mr. Bowen Williams, Mr. F. H. Cheesewright, Mr. E. Wallace, Mr. Carl Brandt, Mr. Alec White, Mr. W. Keast, and Mr. Stanley Graham.—The annual dinner of the society will take place at the Hotel Cecil on Tuesday, June 18th.

Reviews and Notices of Books.

The Science of Hygiene: a Text-book of Laboratory Practice. By WALTER C. C. PAKES, D.P.H., F.C.S., Bacteriologist to Guy's Hospital and Demonstrator of Sanitary Science and Bacteriologist in the Medical School, &c. London: Methuen and Co. 1900. Pp. xv.-308. Price 15s.

THE title of this book is somewhat misleading, as it deals almost entirely with the arts practised by the hygienist in his laboratory. It is, however, a very excellent and useful volume, practical in character, wide in scope, and accurate in detail. It covers the whole of the laboratory work required from candidates for the various diplomas in public health, and, indeed, it covers much more than this, and will be found a good work of reference for medical officers of health generally. We know of no other single book which attempts, much less succeeds in, so wide a field.

The book is divided into five parts. Part I. deals with Bacteriology purely from the laboratory point of view. It gives a full and detailed account of the technique of the subject, including the making of media, and contains a scheme for the examination of the bacteria most important from the hygienist's standpoint, together with an account of the bacteriological investigation of water, air, soil, milk, &c. It appears to be a very adequate and accurate course of laboratory work and cannot fail to be of much utility. We have few criticisms to pass upon it, but we note the use of the term "hypomycetes" for hyphomycetes, and we fail to see what advantage the German word "fleischwasser" has over the English terms "broth" or "meat infusion." In describing the mode of preparing agar-agar plates we find no reference to the convenient method of allowing them to solidify and then inoculating the surface only.

Part II. deals with Microscopic Hygiene and is in many respects the most novel and useful part of the book. It describes the appearances of the different starches, fibres, and parasites which the candidate for a public health diploma is expected to recognise, and the microscopic characters of various foods. This part is illustrated profusely and fairly well, which adds much to its utility. We doubt whether pediculus vestimentorum can be so readily distinguished from pediculus capitis as the author imagines. We should also be glad to learn why the organism of relapsing fever, described as belonging to the bacterial genus spirillum (or spirochæta), is positively stated to be a protozoön, although we know almost nothing about its life history.

Part III. deals with the Chemical Analysis of Water, Foods, and Air, and seems an excellent laboratory guide, founded as it is on the author's own experience. An admirable feature of this, as of other parts of the book, is that everything is explained and not merely stated. We may call attention to a misprint on p. 191, in the equation showing the reaction between silver nitrate and sodium chloride.

Parts IV. and V. deal with Physics and Vital Statistics in a theoretical way and apart from laboratory work. These sections call for no special comment. We would repeat, in conclusion, that Mr. Pakes has produced an eminently useful and practical book which should find much favour with those for whom it is written since it has the great advantage of comprising within one cover information which can otherwise only be gathered from several different sources.

Manuel de Thérapeutique Clinique: Accouchements et Maladies des Femmes en Couches. (Manual of Clinical Therapeutics: Labour and the Diseases of the Puerperal Period.) By M. GAULARD and M. BUE. Paris: Vigot Frères. 1901. Pp. 602. Price 8 francs.

THE importance of the diseases of the puerperal period can hardly be over-estimated, and since it is impossible within the bounds of the ordinary text-book for students to consider them in any great detail such a manual as this is of great service. In the present instance the authors have collected a great deal of information and their own experience and that of others are fully summarised. The teaching is, of course, mainly that of the French school of midwifery and many of the recommendations are therefore novel and at times contrary to English practice as taught in our medical schools. The numerous valuable contributions to the science of midwifery made by such French obstetricians as Pinard, Tarnier, Budin, and Varnier, and the fact that the operation of symphysiotomy is practised to a greater extent in France than in almost any other country, render the perusal of this book of great interest. A manual in the English language dealing with the diseases of the puerperium is at the present time a desideratum, but in the absence of such a book we can recommend students and practitioners either the present work or the well-known monograph of Vinay.

After a consideration of the proper treatment of normal and abnormal varieties of presentation and the treatment of the delivery of the placenta the disorders of the various systems that may occur during pregnancy are described A section upon the Effect of General Diseases upon Pregnancy and the Puerperium follows and then come chapters upon Diseases of the Ovum, Extra-uterine Gestation, Abortions, and Obstruction to Labour produced either by Abnormalities of the Fœtus or of the Pelvis. The two concluding chapters treat of the Various Forms of Septic Infection and the Disorders of the New-born Child.

Modern Medicine. By JULIUS L. SALINGER, M.D., Demonstrator of Clinical Medicine, Jefferson Medical College, &c.; and FREDERICK J. KALTEYER, M.D., Assistant Demonstrator of Clinical Medicine, Jefferson Medical College. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 802. Eight Plates. Price 17s.

THIS is one of those works of which a short review only is necessary. The aim of the authors has apparently been to render the book a synopsis of our present knowledge of medicine without entering into the details as to pathology or theoretical considerations, but we cannot state that a successful text-book is the result, and omissions and errors are constant.

The first part of the volume is concerned with descriptions of physical diagnosis, clinical bacteriology, the examination of the gastric contents, urine, blood, and fæces. There is nothing new in the pages devoted to these subjects.

Turning to the major portion of the work, that devoted to consideration of the various diseases, we again find much to criticise. Pathology receives but scant attention and the symptomatology is frequently insufficiently described. There are some exceptions, however, such as the account of "Infective Endocarditis," which is accurate and well given.

In the description of physical signs, too, the authors again fail in many instances to give a sufficiently full idea to the reader of the many anomalous cases that may occur at the bedside. They describe a characteristic case, but the student who relies on such data will find that there are more exceptions than cases which follow the signs laid down in this text-book. We do not think that the book is likely to become popular in this country.

Materia Medica and Therapeutics, with reference to the Most Direct Action of Drugs. By FINLEY ELLINGWOOD, M.D., editor of the *Chicago Medical Times*. With a Condensed Consideration of Pharmacy and Pharmacognosy by Professor LLOYD, Ph.D., of the Eclectic Medical Institute of Cincinnati. Chicago: Medical Press Co. 1900. 8vo, pp. 706 Price $5 00.

THIS work on materia medica, recognising the United *States Pharmacopœia only in passing* and our *British* Pharmacopœia not at all, will probably not meet with a very cordial reception in the United Kingdom. The parts of the work descriptive of the materia medica are thorough and good and the classification is satisfactory. It is evident that the author is a botanist of no mean order and that he has taken the very greatest trouble to give complete descriptions of every vegetable drug with which he deals. All the medicines are classified as "agents acting upon" one or other system or part of the body, and organic and inorganic drugs find themselves side by side in the same group and chapter. It is probable that the author's therapeutics, however, will not be particularly well received. The style in which therapeutics are dealt with is scarcely scientific; it is over-confident, and members of the profession in England, who are seldom "eclectic," will not be attracted by the statement that hints have been taken "from eminently irregular sources." To be perfectly honest, we are obliged to add that a great deal of the author's introduction suggests that he has approached the study of medicinal treatment from an empiric standpoint. "Eclecticism was originally composed of many dissonant facts. These have been fused or amalgamated until it now has an essentially exact constitution ...... a characteristic individuality which wins for it the approval of all consistent observers." In this style is the book built up, and no one with a sense of humour will fail to glean some amusement from this attempt to make "eclecticism" a school in itself founded on the "gems of truth" gathered and rescued from the teaching of the schools of allopathy and homœopathy and elsewhere.

The Dreamers: An Original Play in Five Acts. By GEORGE H. R DABBS, M.D. Aberd. Shanklin, I.-W.: Silsbury Brothers. 1901. Pp. 45. Price 6*d*.

DR. DABBS has published "The Dreamers" in book form before it has been acted because, as he states in a prefatory note, "no author living amid provincial surroundings, who has not the intention of wasting money on expensive and useless experiments, can ever hope to secure for his work another kind of hearing." We need not discuss the accuracy of this statement at any length, for many things might be said on both sides of the question which it raises without any definite conclusion being reached, and it will be enough to say that "The Dreamers" strikes us as being a better written and more interesting piece than are many of the plays which have been acted and which have secured some measure of commendation, while at the same time it is probably better as a story told in dialogue than it would be if presented without alteration on the stage. It is a drama of modern life in which the principal characters are representatives of Capital on the one side and of Labour on the other, the representatives of Labour being prominent members of continental secret societies which are on the brink of appealing to very extreme measures indeed to bring about their ends. One of the continental secret envoys, actuated by motives that are a little obscure, combines the objects of his society with endeavouring to exact blackmail from the wife of one of the capitalists, a lady who has a past with which another capitalist is connected. But we have no intention of giving away Dr. Dabbs's plot; we have indicated that it is of a sensational, almost of a melodramatic nature, and we need only add with regard to it that it supplies at the ends of Act III. and Act IV. two highly dramatic and interesting scenes which we should say were eminently suitable for stage purposes. The characters are clearly and firmly drawn and their characterisation should become even more marked if "The Dreamers" were ever to see the foot-lights. The drawback to stage production to which we have referred seems to us to lie in the fact that a good deal is talked of at times which is not brought before the audience in the action, whereby occasionally there might arise a little difficulty in following matters of detail that are also matters of importance. A playwright who desires his play to be produced by others, as Dr Dabbs from the note that we have quoted would seem to do, has to remember that managers who may be unwilling to "waste money on expensive and useless experiments" have to consider the intelligence of the audiences for whom they must cater if they want to make money, and that the measure of that intelligence is the hearing and understanding capacity of a rather dull person in the middle of the pit, who will be no deafer or duller than many other persons in the stalls and the dress circle; while neither in stalls nor pit is it possible to turn back, like the reader in an arm-chair, to a previous page in order to pick up a lost thread or to recall what has gone before. Still difficulties of this kind can usually be got rid of by cooperation between a willing author and an intelligent stage-manager, while the same two in partnership might contrive a means of dispensing with Dr. Dabbs's Fifth Act, which from the point of view of stage production is as undesirable as is the proverbial fifth wheel of the coach Beyond this questions of probability as to how much an audience will stand in the nature of anarchist plotters who give their victims cigarettes that kill in a few whiffs, and whether gentlemen and ladies in evening dress control or endeavour to control anarchists from modern English drawing rooms, are elements in the choice of a theatre, but they need not be discussed by a reviewer. "The Dreamers," from a literary point of view, is well worth reading and we commend it to the attention of those who might give it a public hearing to their own advantage.

LIBRARY TABLE.

A Practical Guide to the Public Health Acts: a Vade Mecum for Officers of Health and Inspectors of Nuisances. By THOMAS WHITESIDE HIME, B.A , M.D Dub. Second, much enlarged, edition. London: Baillière, Tindall, and Cox, 1901. Pp 1096 Price 15*s*. net.—This is a veritable mine of information of a somewhat heterogeneous nature, a limp leather-bound octavo volume of lvi. + 1040 pages, with sundry illustrations The first edition of the book was a small, handy pocket volume, but the author in the the second edition has somewhat destroyed the portable character of the volume The book may best be described as a guide to the public health statutes, regulations, orders, by-laws, and memoranda, while it embraces in addition essays upon multitudinous subjects bearing directly or indirectly upon the public health. It is impracticable even to indicate all the contents of this volume, but it may be said that the duly qualified sanitary official will derive much assistance therefrom. We say the duly-qualified official because we feel that the book is more fitted for him than for the student. For the latter the book is, perhaps, a little too complicated, and the rather decided views of the author upon certain subjects render the work more fitted for the matured judgment and critical faculty of the sanitary officer than for the student. Moreover, the scheme of the book is not altogether easy to follow notwithstanding the index and that the Acts are arranged in chronological order. What the author terms "hints" abound in the book and some of such hints are most useful. We have "hints on meat," "hints on statistics," &c., while such subjects as country holidays for poor children, soup kitchens, &c., receive their share of attention. Specimen examination papers for the Diploma of Public Health are within the scope of the volume and in the appendix will be found a selected list of important sanitary law cases which should prove of great value.

Comment la Route crée le Type Social. (*How the Route creates the Social Type.*) By EDMOND DEMOLINS. Second edition. Paris: Firmin-Didot and Co. 1901. Pp. 472. 8vo. Price 3 francs 50 cents.—The actual substance of this work was embodied in a series of lectures given by the author before the Geographical Society in Paris. Drawing largely on the information gained during 25 years' research by M. Henri de Tourville, the author explains to his own satisfaction that the great diversity among the races that have peopled the world has been brought about by the fact that, all originally starting from man's birthplace, the Garden of Eden, different groups have followed different trade routes across the earth and have become modified by their surroundings, so as to form the present social types. There are certain well-recognised great routes of travel and trade over the world, and the author describes in much detail some of, if not all, the types produced by each of these routes. But the work has little or no interest to the ordinary physician or surgeon and is practically an essay in ethnology. There are no illustrations but a few diagrammatic maps.

Transactions of the Society of Anæsthetists. Vol. III. London: Medical Publishing Company. 1900. Pp. 168.—This volume contains a valuable paper by Dr. G. H. Savage on the Relationships between Anæsthetics and Insanity. Although the author finds no evidence of severe mental aberration being initiated in persons who have not had a predisposition to insanity, or actual attacks of insanity, he has met with many individuals among both classes in whom attacks have resulted upon the use of anæsthetics. He admits no difference between various anæsthetics as regards the onset of such attacks nor does he know of any way of obviating the liability to these nerve storms and the subsequent mania. We gather that Dr. Savage would not condemn anæsthesia in the case of those actually insane at the time of the operation and has not found their subsequent condition worse. An instructive discussion upon the "After-Effects of Ether Inhalation upon the Respiratory System," by the members of the society, is given. The conclusions are practically those generally adopted at the present time—viz., that the respiratory troubles following ether are as a rule slight and that when broncho-pneumonia or other serious sequelæ occur they do so as a result of exposure either during the operation or in the subsequent removal of the patient to the ward. Mr. Edgar Willett contributes a useful paper on the Administration and Choice of Anæsthetics for Infants and Young Children and recommends the use of a freshly-prepared mixture of equal parts of ether and chloroform. He gives this by means of a Skinner's frame or double layer of lint, supplying the mixture guttatim from a drop bottle. Some very instructive cases are recorded by Dr. McCardie, Mr. Rickard Lloyd, Mr. Carter Braine, Mr. E. M. Corner, and others. We congratulate the society upon a most servicable volume which must appeal by its own merits to all who take an interest in, or are anxious to keep abreast of, the department of science with which these transactions are concerned.

Royat: Indications Thérapeutiques Méthodiquement Classées. (*Royat: Therapeutic Indications Methodically Classified.*) By Dr. A. BOUCHINET, consulting physician to the Spa. Paris: J. B. Baillière et Fils. 1901. Pp. 104. Price 1*s.* 8*d.*—The mineral springs at Royat have long been recognised as useful medicinal agents in the treatment of anæmia in its various forms and of all painful affections of the joints. The author, who has been practising for the last 10 years as physician at the spa, is anxious to extend the sphere of usefulness of these alkaline waters, and this little book is intended to supply accurate information about everything connected with them. There are four of them, with temperatures ranging from 20° C. to 35° C—that is, from 68° F. to 95° F.—and the mineral salts which they contain vary from two grammes to five and a half grammes per litre. The other diseases which the author claims to be able to relieve or to cure by the use of Royat waters internally and externally are neurasthenia, gouty neuralgias, chronic laryngitis, and the various disorders likely to occur at the menopause. In addition to these are endometritis and the consequent sterility. No records of cases or other references are given.

Records from General Practice. Part II. By J. KINGSTON BARTON, M.R.C.P. Lond., M.R.C.S. Eng., J.P. London: John Bale, Sons, and Danielsson. 1901. Pp. 208. Price 2*s.* 6*d.*—We reviewed the first instalment of Mr. Barton's "Records" in our issue of June 30th, 1900, p. 1889. This, the second number, contains amongst other papers details of 100 cases of midwifery. In those which cover a period of time from June, 1887, to June, 1898, there were no maternal deaths and there was but one death of the child, due to craniotomy. The patient was a primipara, aged 38 years, with a narrow pelvis. During labour she developed acute cardiac dilatation. Dr. W. S. A. Griffith attempted delivery with forceps but failed. Owing to the critical condition of the mother craniotomy was decided upon and delivery was successfully performed. The mother made a good recovery and the action of the heart quickly became normal. Of other papers, those on Drugs and Remedies and the Notes on Urine contain many useful observations.

Mentone as a Health and Pleasure Resort. By D. W. SAMWAYS, M.D. Camb. and Paris. Illustrated by reproductions of numerous photographs. London: Bemrose and Sons, Limited. 1901. Pp. 104. Price 3*s.* 6*d*—This is a small pocket guide with an excellent photograph on almost every other page. If for no better reason than these numerous illustrations, it constitutes a capital little souvenir of the picturesque winter station But there is also a sufficiency of descriptive matter. There is even a brief historical sketch of Mentone extending to the middle ages and describing the various changes that have taken place, including its rebellion from the princely dominion of Monaco and the formation of an independent republic. Of course, such questions as that of the climate are treated at much greater length, for it is the climate which is the main, if not the sole, attraction to Mentone. In this respect the photographs serve better than the text to show how thoroughly Mentone is sheltered from the cold winds and exposed to the hot southern sun. The climate is also vindicated by the vegetation, the orange and the lemon trees, the aloe, the prickly pear, and the violets that appear early in January. The clearness of the atmosphere is proved by the fact that the mountains of Corsica, though 100 miles away, may often be seen across the sea. The advantages which Mentone affords for the climatic treatment of disease are naturally discussed at considerable length and we find that "on the whole phthisical patients are far from being now the bulk of Mentone invalids," but that "half the English doctors who have practised in Mentone came to save their lives and but one has failed." Bronchitis, emphysema, catarrhal conditions generally, cardiac weakness, asthma that is not due to nervous conditions, laryngitis, and renal diseases are all favourably influenced by the climate of Mentone. Dr. Samways also describes the drives, excursions, and diversions generally that visitors may enjoy when wintering at Mentone and has practical advice to give in regard to the hotels, furnished villas, &c. The book will therefore be of use to those who propose to winter at this particular spot.

JOURNALS AND MAGAZINES.

American Medicine. Vol. I., Nos. 1 and 2.—This is a new medical journal and is, as we learn from the title-page, "founded, owned, and controlled by the medical profession of America." Among the writers of original articles we see such well-known practitioners as Osler of Baltimore, Hare of Philadelphia, and Deaver of Philadelphia. The type is good, the paper is good, and the editorial comment, as might be expected from such an editor as Dr. G. M. Gould, is bright, pithy, and interesting. A feature of the journal is the "World's Latest Literature," which is a well selected *résumé* of medical literature from other journals. We were pleased to see in the prospectus affixed to No 1 that "the reading columns will not be dominated or influenced by commercial considerations. Not a 'reading notice' will ever appear if watchfulness can prevent. Any attempt to bribe or intimidate editorial action—and such attempts, positive or negative, are common—will fail." It was with some surprise, therefore, that we saw at the end of the journal three pages given up to a record of the use of two drugs in certain diseases, exemplified by reports of cases and illustrated with temperature charts. For these articles, which at first sight appear to be original articles, are in fact mere reprints from back numbers of other medical journals and are advertisements pure and simple, only printed to look as if they were not so. The list of founders and subscribers to the new journal includes some of the most honoured names in American medicine. It is therefore to be hoped that the advertisements will not appear again in the objectionable form to which we have referred. They are still in evidence in No. 2 and are in this number even more like "reading matter" than in No. 1, for in that number they were divided from the journal proper by a list of subscribers. But we are confident that this little incongruity has escaped the eye of the editor and will promptly be set right. Dr. Gould, if only by reason of his wonderful "Illustrated Dictionary of Medicine, Biology, and Allied Sciences," is entitled to the gratitude of every English-speaking medical editor, and we cordially wish him success in his new venture.

The *Practitioner* continues in the May number its consideration of organo-therapy. Dr. W. E. Dixon contributes a commendably concise yet interesting article on the Composition and Action of Orchitic Extract. He concludes that injections of this extract as administered by Brown-Séquard have a powerful influence in metabolism and on blood-pressure. The metabolic effects are shown by changes in the blood and urine. Dr. Dixon also discusses the ovary as an organ of internal secretion. A case of transplantation of an ovary from one woman to another is quoted. Dr. W. Bulloch summarises recent work on the nature of cytotoxins. Dr. C. R. Box writes on the value of suprarenal preparations in Addison's disease, discussing two cases very carefully observed over considerable periods of time. There is very little evidence as yet of benefit in Addison's disease from suprarenal extract. An article on the recent work of some French authors deals with their conclusions as to the therapeutic value of extracts from various organs. Some remarkable effects are quoted, particularly as regards liver extracts used in cases of diabetes and intestinal extracts in cases of obstruction of the bowels. The hero of medicine for the month is Brown-Séquard whose restless and effective life is succinctly told. The editorial remarks deal mainly with the question of army medical reform The affairs of the National Hospital for the Paralysed and Epileptic, Queen square, W C., are also discussed, and Mr Burford-Rawlings is very justifiably castigated. Dr. Arthur Newsholme writes on ventilation of schools, and there are, as usual, good summaries of recent work in one or two departments of medicine.

The *Medical Magazine* is not very interesting in its May issue. Mr. J. Foster Palmer allows the account of modern epidemics to lead him from the consideration of cholera to the investigation of infinity We want more physics and less metaphysics in such articles. Mr. A. R. Whiteway upholds the Elmira method of treating criminals. Dr. Thomas Oliver writes on health in the school and some good advice as to ventilation and spread of infection in schools is to be found in his article.

# Analytical Records
FROM
THE LANCET LABORATORY.

PLASMON COCOA.

("INTERNATIONAL PLASMON," LIMITED, 66, DUKE STREET, GROSVENOR SQUARE, LONDON, W.)

PLASMON cocoa is typical of the undoubted advantages that may be gained by the addition of plasmon to a common article of diet. Plasmon increases the food value of cocoa enormously, more than half of the resulting mixture consisting of pure and soluble proteid Raw cocoa is, of course, unsuitable dietetically chiefly because of the large proportion of indigestible fat which it contains. In the best cocoas this fat is reduced to about 30 per cent. from an initial quantity of 50 per cent. The proteid value of cocoa is, however, small, for out of a total amount of 20·85 per cent. only 6·4 per cent, according to a recent analysis which we have made, is soluble Some of the nitrogen of cocoa occurs in the interesting alkaloid, theobromine, an ally of caffeine, in tea, and in coffee, the amount of theobromine being nearly 2 per cent Though cocoa is to some extent nutritive, yet its value as an article of diet is chiefly due to its stimulant properties, and its freedom from irritating substances has made it a satisfactory substitute for coffee and tea where these cannot be tolerated. With milk and sugar cocoa forms an excellent beverage and one which presents the composition of a food in accordance with physiological requirements. The remarkable nutritive power of plasmon has been well-established, and, as we have already pointed out, plasmon may be used with the greatest possible advantage to enrich food otherwise poor in nitrogen or proteid Plasmon cocoa contains all the constituents able to support life. It is mildly stimulating whilst highly nourishing Our analysis was as follows: moisture, 10·82 per cent; mineral matter, 7·50 per cent.; proteids, 57·51 per cent, fat, 10·20 per cent.; and starch and insoluble matters, 13·97 per cent Further analysis leads to the satisfactory result that as much as 92 per cent. of the total proteid of plasmon cocoa is in a soluble state. The cocoa used in plasmon is of excellent quality, possessing the well-known cocoa flavour and aroma to a marked degree whilst containing a minimum of fat—namely, 29·10 per cent. Since plasmon contains at most only a trace of fat, the fat present in plasmon cocoa is wholly derived from the cocoa mixed with it. These figures would accordingly show that plasmon cocoa contains 35·43 per cent. of cocoa and

64·57 per cent. of plasmon. There are many substances mixed with cocoa to which exception may be taken, but the admixture of a soluble proteid which is a rapidly assimilable food is a physiologically correct proceeding, making cocoa a very nourishing article, an advantage which in its natural state it lacks. The addition of plasmon to cocoa, moreover, whilst not detracting from the dietetic properties which it possesses, reduces the fat to a more easily digestible quantity. Plasmon cocoa is an important and valuable adjunct to the every-day dietary and offers an advantage in special dietetics also.

(1) HEROIN PREPARATIONS; AND (2) ELIXIR OF IRON AND MANGANESE PEPTONATES WITH AND WITHOUT CREASOTE

(SCHIEFFELIN AND CO , NEW YORK. LONDON AGENCY POTTER AND SACKER, 7, FOWKES-BUILDINGS, GREAT TOWER-STREET, E C)

We have received a very interesting and elegant series of preparations containing heroin which has been used favourably in the place of morphia as a sedative, particularly in respiratory affections. "Elixir eupnein" contains per fluid ounce one-sixth grain of heroin with eight grains of terpin hydrate and 20 grains of creasote. This preparation has been used in the treatment of pulmonary tuberculosis, chronic bronchitis, and other chronic affections of the lungs. "Elixir heroterpin" contains the same ingredients except the creasote. The combination appears to be valuable in bronchitis and asthma. "Syrup herophosphites," besides containing the hypophosphites of iron, manganese, lime, quinine, strychnine, &c., contains also per fluid ounce four-thirtieths of a grain of heroin. The same preparation may be had free from sugar. The soothing effect of heroin is said to be attended with distinct advantage in this combination. Lastly the preparation known as "Elixir of Iron and Manganese Peptonates with Arsenic" is worthy of mention. Each fluid ounce contains the so-called peptonates of iron and manganese in the quantities of 34 grains of the former and 8½ grains of the latter and one-thirtieth of a grain of arsenious acid. The "Elixir creoferrate" contains in each fluid ounce the same quantities of the peptonates and two grains of creasote, but the arsenic is omitted. This preparation is intended for the treatment of chronic affections of the respiratory organs attended with anæmia. The creasote serves to arrest fermentative dyspepsia.

(1) PEPTO IODO-EIGON; AND (2) PEPTO-BROM EIGON.

(THE HELFENBERG CHEMICAL WORKS CO , LONDON AGENCY, MESSRS. BUCHNER, SCHACHT, AND CO , 55, FORE STREET, LONDON, E C.)

The iodo- and brom-eigons are albuminous compounds of iodine and bromine respectively. Soluble modifications of these compounds are formed by associating them with peptones. As much as 15 per cent. of iodine is contained in pepto-iodo eigon and 11 per cent. of bromine in pepto-brom-eigon; both compounds are easily soluble in water, the solution possessing a meat-like flavour with somewhat bitter and inky aftertaste. The preparations are fine amorphous light brown powders. The peptone reaction is characteristic of each. The halogen can be expelled by heating with nitro-hydrochloric acid. The comparatively large quantity of iodine and bromine respectively contained in these organic combinations is remarkable. They are intended for the administration of iodine and bromine where the ordinary mineral iodides and bromides are badly borne. It is said that no irritation of the mucous membrane or other unpleasant symptom is set up after the administration of pepto-iodo-eigon, as is sometimes the case with potassium iodide, while the pepto-brom-eigon produces no ill-effects as do the ordinary bromides at times, such as giddiness or skin eruptions, even when administered continuously and in large doses. The iodine preparation has been employed in gynæcological practice and in syphilis. These curious halogen albumin derivatives are of great interest both from a chemical and therapeutical standpoint.

CAMBRIDGE LEMONADE

(CHIVERS AND SONS, HISTON, CAMBRIDGE.)

We have carefully examined this preparation for the common impurities of its kind, but without a positive result. The materials are pure and wholesome, being obtained, as it it stated, from selected lemons. The preparation has the appearance of brown sugar which dissolves easily in water, producing a yellow opalescent liquid (an opalescence due to lemon oil) similar to lemon squash. It possesses the pleasant aroma and acid taste of the fresh-cut lemon and affords a refreshing and agreeable summer beverage.

PROTENE DIABETIC BRAN BREAD.

(THE PROTENE CO., LIMITED, 35, WELBECK-STREET, CAVENDISH-SQUARE, LONDON, W.)

This is a brown loaf of good uniform texture and indifferent flavour. Our analysis gave the following results: moisture, 38 60 per cent.; mineral matter, 4·70 per cent; proteids, 25·09 per cent.; fat, 11·25 per cent.; and non nitrogenous matter, including starch, 20 36 per cent. The bread, as will be seen, contains an excellent proportion of proteid representing the separated casein of milk. It is not, however, free from starch but contains a minimal proportion. The fat occurs also in notable amount, over 10 per cent The bread is regarded as useful for the relief of constipation owing to its branny constituents.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia was held on May 9th, Sir WILLIAM SELBY CHURCH, the President, being in the chair.

The following Members were admitted as Fellows of the College: William Burns Beatson, M.D. St. And. (Eastbourne); Arthur Hamilton Nicholson Lewers, M.D. Lond.; John Walter Carr, M.D. Lond.; Edmund Hobhouse, M.D. Oxon. (Brighton); William Rivers Pollock, M.B Cantab.; Hugh Walsham, M.B. Cantab.; Walter Sydney Lazarus-Barlow, M D. Cantab.; Edmond Fauriel Trevelyan, M.D. Lond (Leeds); John Hannah Drysdale, M.D. Cantab; Frederick Eustace Batten, M.D. Cantab.; Raymond Henry Payne Crawfurd, M.D. Lond.; and George Frederic Still, M.D. Cantab. The admission of Dr. W. J. Tyson was unavoidably postponed

Dr. Norman Moore was elected by a large majority as the Representative of the College on the General Council of Medical Education and Registration for a term of five years from May 14th, 1901.

On the motion of Dr. NORMAN MOORE, seconded by Dr. JAMES TAYLOR, a report from the Committee of Management on a letter, dated Dec. 12th last, from the General Medical Council, inclosing a resolution of the Council with respect to the registration of medical students, was fully considered, and it was adopted by a very large majority. The following Fellows took part in the discussion: Dr. D. MACALISTER, Dr. P. H. PYE-SMITH, Sir R. DOUGLAS POWELL, Dr. P. W. LATHAM, and Dr. J. F. PAYNE.

The PRESIDENT announced that the following Fellows had been appointed to serve on a joint committee of the two Colleges to consider the position of the Colleges in relation to the newly organised University of London: the President, Dr. Pye-Smith, Dr. W. H. Allchin, Dr. J. Kingston Fowler, and Dr Norman Moore.

Dr. THEODORE WILLIAMS was appointed as the delegate of the College to the British Congress on Tuberculosis to be held in London from July 22nd to the 26th inclusive.

Permission was granted to Mr. Rischgitz to take photographs of the portraits of the Munro family in possession of the College.

The report from a special meeting of the Censors' Board, held on April 29th, recommending that the diploma of a Licentiate should be suspended for two years, was received and adopted.

THE LANCET.

LONDON: SATURDAY, MAY 18, 1901.

The General Medical Council and the Royal Colleges of Physicians of London and Surgeons of England: a Deplorable Impasse.

THE five years' curriculum of medical study, which has now been in operation for about nine years, has been the source of unexpected controversy between three of the leading bodies connected with medical education. The dispute in question is only of about 18 months' standing, but it appears likely to result in a deadlock since neither of the disputants seems inclined to yield, and if it should continue the system of registration of students by the General Medical Council will be imperilled. When the extension of the curriculum was adopted it was with the hope that more time would be afforded to the student for the clinical and practical part of his work. We are far from saying that something has not been gained in this direction, but at the same time it is notorious that the chief use made of that additional year has been to utilise it for the earlier part of (so-called) medical studies, for work which is not strictly speaking medical but scientific; and the whole trouble has arisen from the refusal of the two Royal Colleges of Physicians of London and Surgeons of England to be bound by the General Medical Council in their selection of institutions where these preliminary studies may be carried on. For the General Medical Council requires that "no medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced his medical studies at a university or school of medicine, or at a scientific institution recognised by one of the licensing bodies and *approved by the Council.*" It is around the claim represented by the words which we have italicised that the whole controversy is centred.

As in most disputes between reasonable persons there is something to be said on both sides. The General Medical Council, composed as it is largely of representatives of the medical corporations and universities of the United Kingdom, including those of the two recalcitrants, is no doubt keenly desirous of maintaining a high level of education all round. Its requirements as regards the preliminary examination in arts of intending medical students are by no means excessive; many people think they are not stringent enough. But they have been accepted by licensing bodies as adequate, and none of these bodies, except the universities, show any desire to establish examinations in these extra-curricular subjects. The next stage in the student's career is the one where the difficulties arise. He is supposed to commence his medical studies when he is really entering upon a course of physical and natural science such as he can often acquire at the school whence he matriculated, as well as at many an institute of science which has no reference to the career which he is assumed to have already entered upon. The General Medical Council having imposed a five-years' curriculum from the commencement of medical studies cannot ignore this period of the youth's career, and with a solicitude which testifies to its desire for a common standard declines to recognise him as a medical student at all unless he has pursued these scientific studies at a place of which the Council approves. Now, the Council does not apparently approve of all the institutions which after investigation have been accepted as suitable places of study by the two Royal Colleges in question; and the latter, who are just as anxious as the former body to maintain a high standard of education, resent the supervision of their choice by the Council. It seems a small matter, but from the point of view of the Colleges it does involve a principle for which they are perhaps scarcely to be blamed for striving to maintain, except in so far as they may be setting a bad example in opposing constituted authority. No one can say that the Colleges are not just as competent to recognise good from bad schools as is the General Medical Council; they have within their bodies some of the most prominent and experienced medical teachers in the country, whilst their diplomas are deservedly recognised as of high value. The principle at stake in their view is one which is common to all corporations and universities—namely, the right to frame their own regulations of study required from candidates for their diplomas and degrees. And so long as instruction in these preliminary scientific subjects is considered as part of medical education, every medical licensing body technically has the right, if it chooses to exercise it, of determining from what scientific institutions it shall receive certificates.

Until this country has a State diploma-granting body it is hopeless to expect equalisation in the value of diplomas, and regrettable as it may be for individual corporations to take their own line in these matters we fail to see how it can be avoided under present circumstances. We trust, however, that an amicable settlement of this particular matter will be arrived at between the Colleges and the Council. There ought to be a way out of the *impasse.* The General Medical Council, for instance, might "gracefully concede" its approval of all scientific institutions selected by the Royal Colleges, or it might boldly declare that these subjects are no longer to be considered part of the medical course and place them on their proper footing of "preliminary education." In that case we conceive that corporations will hardly dispute the right of the Council to make its own regulations and requirements for a preliminary scientific examination to be passed not earlier than 12 months from the date of the preliminary examination in arts. This may seem to some educational authorities, especially those who feel that medical education in this country is not scientific enough, to be a retrograde step. But it is only in accordance with the tendency of the age, and for our part we do not think that many medical schools will be sorry to be relieved of the burden of teaching elementary science that they may be enabled to devote their energies to the sciences as applied to medicine. After all it will only be doing what the University of London has done for half a century, only the University does not even care where its candidates pick up their science so long as they can pass the preliminary scientific examination. It is true that the University enforces its right of testing the candidate's knowledge by its own examinations, whereas the Colleges and other corporations accept the tests of other bodies as evidence of sufficient knowledge. But if it were recognised by the Council as a purely preliminary study there is no reason that we can see why the selection of the test sufficient to qualify for registration should not be given over to that body just as is now practically done in the case of the earlier arts education. We make the suggestion in all seriousness and trust that it will not be deemed unworthy of consideration by the General Medical Council and the bodies represented thereon.

Coincident Typhoid and Malarial Infection.

SINCE WOODWARD in 1862 introduced the term "typho-malarial fever" there has been a long-waged controversy in medical literature on the question of the existence of such a disease and its nature. In the Johns Hopkins Hospital Reports, vol. viii., 1900, is a very interesting contribution by Dr. J. P. LYON of Buffalo on the subject, but the author prefers to discuss the matter by considering the coexistence of typhoid and malarial infection in the same subject, and the clinical picture resulting from such a combined infection rather than to adopt the term to which we have referred—"typho-malarial fever." He points out that so long as the exact cause and nature of both typhoid fever and malarial fever were unknown it was not a matter of surprise that little headway was made toward solving this problem. But as the cause and nature of these diseases have been established by scientific demonstration investigators are more in a position to settle the controversy.

Dr. LYON has carefully collected from literature 29 cases which have been thoroughly investigated, and he adds a case that was under his own care in the Johns Hopkins Hospital. He likewise discusses the various views which have been brought forward in favour of the term "typho-malarial fever," a term employed by WOODWARD, a surgeon in the United States Army, to describe cases of fever which presented a clinical picture neither of typhoid fever nor of malarial fever, but apparently a compound of both. In 1876 the same observer read another paper at the meeting of the International Medical Congress in Philadelphia, in which he maintained that "typho-malarial fever is not a specific or distinct type of disease, but the term may be conveniently applied to the compound forms of fever which result from the combined influence of the causes of the malarious fevers and of typhoid fever." Dr. LYON therefore examines his series of 30 cases to extract from them what evidence they offer on the subject of the so-called "typho-malarial fever" and on the question of the relative frequency of the combined infection. The descriptions of the clinical aspects have hitherto been supplied mainly by American and French observers, and a marked difference is found between them. For instance, American physicians maintain that rose spots seldom develop; that the course of the fever is shorter and markedly milder than that of typhoid fever; and that the prognosis is consequently highly favourable and the mortality is very low. On the other hand, most of the French writers state that the course of the disease is usually severe and the mortality high; that complications are common; and that rose-spots usually appear. Dr. LYON concludes that, as a rule, the course of the disease is of at least average severity as compared with typhoid fever, and generally of greatly increased severity. The mortality in his series was high—in fact, it was about double that of typhoid fever, basing the statistics of typhoid fever on a large number of cases collected through a long period of years from different climates and regions of the world. With regard to the clinical picture no uniformity was found. The typhoid picture, however, was always present and in nearly all of the cases dominated the scene. The malarial manifestations appeared at different points in the different cases. Repeated paroxysms of chill, fever, and sweating at the onset of the disease appeared in many of the cases; in others these features were absent. Occasionally febrile paroxysms occurred during the height of the disease and irregularly through its course, though this was the exception. In most cases the malarial paroxysms occurred only in the convalescence from the typhoid fever. It is interesting to note also that in several cases malarial paroxysms directly preceded or accompanied the onset of the typhoid fever, disappeared completely during its course, and again reappeared during convalescence. This would seem to indicate, as BACCELLI, LAVERAN, and others have suggested, that the typhoid fever is the more masterful disease, and to illustrate the truth of the old adage, "De duobus morbis corpus unum obsidentibus potior alterum obscurat." Dr. LYON points out, however, that the important fact must not be forgotten in this connexion that quinine was freely used against the malarial element whenever it appeared, and in all probability, in some cases at least, completely changed the clinical picture that would otherwise have been manifested. He is convinced that had the malarial involvement been left untreated to pursue its own course the composite clinical picture would have been occasionally very different from what it actually was after quinine had removed the malarial participation in the course of the disease.

The series of cases studied by Dr. LYON strongly supports the observations of the French writers who have described a "typho-malarial fever," and he believes that this fever is a true coincident typhoid and malarial infection; but the "typho-malarial fever" described by the American writers as being so prevalent in the United States, and especially in the Southern States, is not, he says, as a rule, a true combination of typhoid fever and malarial disease. The important point of difference clinically between the "typho-malarial fever" of American and French physicians is found in the severity and mortality of the disease. The statistics of the United States army during the Civil War show the mortality from "typho-malarial fever" to have been less than one-fourth of the mortality due to simple typhoid fever. Dr. LYON is therefore quite justified in concluding that the "typho-malarial fever" reported during the Civil War was not true combined typhoid and malarial fever, but either, and usually very mild, typhoid fever or continued malarial fever. Dr. LYON's remarks are well worthy of careful perusal. He selected his cases with great care; they were all proved to be cases of combined typhoid fever and malarial infection by the existence of the parasites of malarial disease in the blood and by strong evidence, clinical, pathological, and bacteriological, of true typhoid fever. All the more recent investigations go to show, then, that the term "typho-malarial fever" to express a distinct disease should be dropped; and the fact that the combined infection does exist fully explains those cases of typhoid fever with a high mortality and abnormal temperature chart which are met with in regions where the malarial poison is rampant.

The Etiology of Cancer.

IN the May number of the *American Journal of the Medical Sciences* appears a very important paper by Dr. HARVEY R. GAYLORD on the Protozoon of Cancer. It is now many years since the idea first arose that malignant disease might be caused by the local action of some micro-organism. Most of the earlier observations did not lead to any definite result. Nearly all the attempts at cultures were unsuccessful, but in 1887 SCHEUERLEN described a special bacillus, and KUBASOFF claimed to have produced secondary growths after the injection of a bacillus which had been obtained from a case of carcinoma. As these results were not confirmed by other observers it was concluded that these organisms were due to accidental contamination and that they were in no way connected etiologically with the malignant disease. The opponents, moreover, of a microbic origin of cancer were very emphatic as to the unlikelihood of any organism being the cause of carcinoma, and they claimed that no theory could be formulated which would account satisfactorily for all the phenomena of the occurrence and the progress of malignant disease. They explained, to their own satisfaction at least, all the facts connected with cancer by ascribing them to alterations in the nutrition of the organs involved or to a loss of the control of the nervous system.

Although many of these explanations were specious, it was felt by other observers that a microbic cause would better serve to account for the mode of occurrence and growth of the disease. Without laying too much stress on "cancer houses" and similar phenomena, pathologists recognised that the geographical distribution of cancer was in itself sufficient to discredit the idea of a nervous etiology, and the suggestion that the cause of the disease might be microbic, and yet that the organism might not belong to the class of bacteria, served to stimulate speculation and investigation. Histological observations showed within many of the cells of new growths various abnormal appearances which were explained by the supporters of the microbic origin of the disease as due to the presence of organisms, while their opponents as firmly held that they were nothing but degenerated cells. Most of those who acknowledged the parasitic nature of these cell inclusions were inclined to refer them to a branch of the protozoa—namely, the sporozoa or psorosperms, as they are frequently called. The coccidium was the genus to which the supposed micro-organism of carcinoma was ascribed, and, indeed, the coccidium is parasitic in many animals, and in rabbits does produce tumours in the liver, but these tumours bear no resemblance to carcinomata. Psorosperms have definitely been found in Paget's disease of the nipple, and this disease invariably leads to cancer of the breast if allowed to continue unchecked; or, rather, it may be looked upon as malignant from the commencement. All observers, however, have not agreed in considering these special hyaline bodies to be members of the class of protozoa, for there has been on the part of many a disposition to look upon them as yeasts. In 1890 RUSSELL described some spherical bodies in cancerous growths which were best demonstrated by the aid of fuchsin, and so he gave them the name of "fuchsin bodies." He considered that they belonged to the yeast group. In 1898 SANFELICE of Sardinia published a series of articles which went to prove that the parasitic inclusions found in cancer were identical in appearance with yeast organisms which had been injected into the tissues of animals, and he described some tumours which he had produced by inoculation with a yeast. One yeast which SANFELICE obtained from the skin of a lemon produced granulomata when injected into animals, and after the organism had been passed through several dogs its virulence had much increased, and when this yeast was injected into the breast of a dog it was followed after some months by the appearance of a true carcinoma. SANFELICE, however, was unable to obtain cultures of the organism from this growth.

In 1899 an article by PLIMMER appeared which described a new method of staining for showing these cell inclusions, and by this method he was able to demonstrate conclusively many facts in connexion with these bodies. His statements were based on the examination of 1278 specimens of cancer, and in 1130 of these he found the bodies which he considered to be parasites In one instance PLIMMER was able to obtain a culture from a cancer; it was from a rapidly-growing carcinoma of the breast and it proved to be a yeast. Several other observers have also claimed to have found yeasts in cases of carcinoma. This represented the state of our knowledge when GAYLORD took up the investigation of the subject in the New York State Pathological Laboratory. The first portion of the work was a systematic investigation as to whether PLIMMER'S bodies occur invariably in all malignant growths, and it was found that in all the cases of carcinoma which were examined PLIMMER's bodies were uniformly present. In all these tumours RUSSELL'S fuchsin bodies were also seen in large numbers. In attempting to determine the nature of PLIMMER'S bodies it soon became evident that many observers have described these structures. The variations which occur in the illustrations depend probably on the different methods of hardening and staining employed by the different investigators. So it is obvious that PLIMMER'S bodies are not new structures, but his hardening and staining methods give them a more uniform appearance and apparently enable them to be recognised in some cases where the ordinary methods give no results. GAYLORD was unable to demonstrate the identity between PLIMMER'S bodies and transformed yeast organisms, and he concluded that they are not yeast cells. In a case of carcinoma of the abdomen GAYLORD found in the peritoneal fluid a number of minute, homogeneous, pale spherical bodies which were at first taken for droplets of fat, but it was soon seen that their refractive index was too low for fat. They were also unaffected by ether and by solution of potash, and did not stain black with osmic acid. Some of these bodies were injected into the jugular vein of a guinea-pig and when the animal was killed a month later a carcinoma of the lung was found. The first attempts at cultivating these organisms were not successful, but later better success was obtained, and it was found possible in many cases to cultivate them directly from cancerous growths and from fluids in contact with cancer. The development of the organisms was watched and they were seen to throw out pseudopodia, to develop a nucleus, and to become spore-sacs. These bodies are those described by PLIMMER and are best differentiated by his method of staining. It was further found that RUSSELL'S fuchsin bodies were the smaller spheres which were more resistant to fixatives. GAYLORD is satisfied that the organism is a protozoon and not a yeast.

We have been able to give but a very brief account of these recent investigations, but the care and skill with which the researches have been carried out must be apparent to all who read Dr. GAYLORD'S interesting paper, and though it would be premature to express any decided opinion until the investigations have been confirmed by other observers, yet the results are very probable and serve to explain and to reconcile many observations which were apparently inconsistent. Should they be confirmed, a very decided step will have been taken in the pathology of malignant diseases, and though a knowledge of the etiology of a malady is very far from being a knowledge of its cure, yet we may reasonably hope that a full acquaintance with the mode of causation of cancer will assist us greatly in preventing the occurrence of the disease.

Annotations.

"Ne quid nimis."

LUXURY IN DIET.

IT is a well-known fallacy that eating is necessarily feeding, but there is no doubt that many individuals eat an average daily amount of food far in excess of what is really required in order to sustain the vital processes. That being so, the waste of food is very great, for the digestive organs are not able to deal with, or to appropriate, the large quantity of food which a person is tempted by his appetite to take. This is one aspect of the question of economy in food which deserves consideration, and undoubtedly if more attention were given to the rational relationship of appetite to the needs of the system we should be all the better for it. But there is another aspect of the question equally worth considering, and that is in connexion with luxurious foods. Of course, the wealthy man pays a good deal more for his breakfast, luncheon, and dinner than does the poor man, but is Dives physiologically and physically speaking any better for it? We doubt it. Plain food is, on the whole, more acceptable to the economy than are rich morsels. It is very questionable whether from the strictly nutritive point of view champagne and oysters are after all in health an advance upon ginger-beer and cockles, whether turtle is preferable to calf's head, or caviare to soft herring roe, or plovers' eggs superior to the ordinary eggs of the barndoor bird. But there is a vast difference between the price of champagne, say at 10*s.* a bottle, and ginger-beer at a penny a bottle, and between oysters at 3*s.* 6*d.* a dozen and cockles at 50 for a penny, and between turtle soup at 10*s.* 6*d.* a pint and calf's head soup at 6*d.* a plateful. We shall be pretty correct in stating that the man who buys common eggs instead of plovers' eggs, and calf's head instead of turtle, and a pigeon instead of a partridge, is the gainer, at any rate from the economically nutritive point of view. In other words, the price of an article of food by no means sets upon it its food value and the difference represented between the price of champagne and ginger-beer, between that of oysters and cockles, &c., is the price paid for pleasing the palate, which extravagance is probably the penalty of a mental rather than of a bodily demand. But physiologically it is akin to substituting diamonds for coals in the steam-engine. Luxurious foods are, strictly speaking, creature comforts, while plain foods are bodily necessities. It must be admitted, however, that, as a rule, choice-tasting game and meats are necessarily tender and therefore easy of assimilation. But clearly there must be a limit to the appropriation of food by the body, and this limit may be reached just as easily by means of good, plain, and tender food as by food of a rarer sort. According to this view there must be great physiological extravagance going on from day to day. In the matter of beverages the same sort of extravagance occurs. Enormous prices are given for a particularly choice wine, but here, again, it is practically certain that the human economy gains little or nothing by it. Does the man who drinks a claret of choice vintage at, say, 10*s.* a bottle obtain any material advantage over the man who drinks his shilling bottle of *vin ordinaire?* It is doubtful. In any case, the prices asked for wine at big hotels are so monstrously high and the wine offered is so often bad that this fact alone accounts for an increasing demand for whisky as a dinner beverage. There are obviously considerable physiological sin and wantonness committed in the choice of food and in the quantity consumed.

THE METROPOLITAN WATER-SUPPLY.

THE Water Examiner to the Local Government Board has
issued his report on the condition of the metropolitan water-
supply during the month of March. The Thames water
was coloured and turbid during the first 12 days of the
month, and from the 1st to the 8th of the month the engineer
of the Chelsea Company closed the intake from the river.
According to the statement which he has supplied the
Thames water was of "indifferent" character on the 1st of
the month and "bad" from the 2nd to the 8th, both days
inclusive. It is very much to be regretted that Dr. T. E.
Thorpe, the chemist appointed by the Local Government
Board to examine the quality of the London water-supply,
did not make a full analysis of the water supplied by each
company during the period in which the river was in flood
and the water was turbid, [illegible]ation of [illegible] East London Water Company
has no subsidence rese[illegible]ortant point of di[illegible] Thames supply, and
at the period when the[illegible]arial fever" of A[illegible] considered by the Chelsea
Company's officer to b[illegible] the severity a[illegible] that it should not be taken
at all the East Lond[illegible] of the United [illegible] Company was presumably taking
similar water and pump[illegible] mortality fro[illegible] it directly to its filter beds at
Hanworth. If this wa[illegible] the fact it would have been
interesting to learn w[illegible] than one-fourth of [illegible] the quality of the water supplied
from the Hanworth filter. Dr. LYON [illegible] actually was. Dr. Thorpe

full analysis of one specimen of the water of each company was made on March 18th, and the specimen taken of the East London Company's water came from a cab-rank in Shoreditch. It is not too much to say that the quality of the water filtered at Hanworth on March 2nd is not to be gauged by the quality of the water supplied at a Shoreditch cab-rank on the 18th of the same month. The average daily amount of water supplied by the metropolitan companies was 195,914,944 gallons which it is estimated represents a daily consumption of 31·63 gallons per head. The average daily amount per head supplied by the Chelsea Company was slightly more than that given in the corresponding month of the year 1900, but in the case of all the other companies the daily supply per head was less than it was in that year. During the month under review the number of new supplies given by the water companies was 2045, but no information is given in the report as to the districts in which this extension has taken place. Although all the water companies are under a statutory obligation to give constant service to all their customers, this duty is still flagrantly neglected and the report shows that the Lambeth Company gives a constant supply in only 76 3 per cent. of the total number of its supplies. This company is privileged to exact a higher water rental than is permitted in the case of any other metropolitan company. According to the analysis of Dr. Thorpe the Grand Junction Company has supplied water containing the highest proportion of organic carbon. The same company has supplied also the dirtiest water, or, to adopt the polite euphemism of the Water Examiner, that containing "the deepest average tint of brown." The report states that the average rate of filtration per square foot per hour adopted by the company was 1·12, this rate being more rapid than that in use by any of the other companies. The reservoir capacity of the Grand Junction Company is undoubtedly another cause of the unsatisfactory quality of the water supplied. In the case of the Grand Junction Company the reservoirs for the storage of unfiltered water are sufficient only to contain an amount equal to 2 9 days' supply, whilst the West Middlesex Company has storage capacity sufficient for 18 7 days' supply.

GERMAN SCIENTIFIC AND MEDICAL LITERATURE IN THE EIGHTEENTH CENTURY.

THE *Frankfurter Zeitung* in a recent issue publishes an elaborate and, from the point of view of the historian, a well-studied account concerning literary publications in Germany during the eighteenth and the last century, and we note with satisfaction that special prominence is given throughout by the writer of this highly interesting and instructive composition to medical and scientific literature. Without entering into any special details it deserves to be pointed out that during the eighteenth century the increase in the output of books was more or less gradual and reached its acme in the years immediately preceding the French Revolution. The year 1786, however, stands out as by far the most prolific both as regards the publication of books in general and especially the inauguration of the use of the more comprehensive scientific treatises commonly called "Handbücher." In that year the number of books published amounted on the whole to several thousands; of these there were: purely medical, 275; scientific (chemistry and physics), 162; political and physical geography, 147; and mathematics, 49. It is interesting to record that there were, in addition, some 135 journals already in existence; they were, it is stated, founded exclusively for the purpose of publication of matter of a purely literary and scientific character, and they are still to a considerable extent preserved in a good condition in the library attached to the University of Leipsic; moreover, we are informed that both a classified index and a subject catalogue are kept there separately to facilitate reference to this rather old fund of learning. In connexion with this statement it may be of interest to observe that Leipsic, which still has a world-wide reputation for great literary enterprise, was then almost the only publishing centre in Germany.

THE BIRMINGHAM CONSULTATIVE INSTITUTION.

THE honorary secretary of the Birmingham Consultative Institution has published certain resolutions approved by his committee under which the institution guarantees (1) that in the future all advertisements will be avoided; (2) that none of the promoters will receive financial benefit from the operations save the medical staff; and (3) that only those patients will receive attention whose means warrant their recourse to the institution. In these circumstances applications for appointments are invited from the medical profession. We recommend our readers to wait before applying for these posts. The medical profession in Birmingham do not consider that a Consultative Institution is in the least required in their city and our opinion is the same The consultant surgeons and physicians of Birmingham, men with hospital practices and other claims to large and special experience, have offered to see all cases which are introduced to them by medical men as deserving of the concession at greatly reduced fees, so that there is no necessity for an institution managed by laymen to meet the wants of those who in the opinion of laymen can afford to pay only low fees. The institution proposes to provide by an elaborate machinery facilities that have already been offered to the Birmingham public by the medical profession. We shall not be surprised if the medical profession of Birmingham receive with coldness their professional colleagues who accept posts under the lay managers of the Birmingham Consultative Institution.

HEREDITY AND DENTAL DISEASE.

AT the last meeting of the Odontological Society of Great Britain a paper was read by Mr. Norman G. Bennett entitled Heredity and Dental Disease. As an introduction to the more special details connected with the teeth and jaws the author briefly reviewed some of the facts of inheritance and the theories which have been enunciated from time to time to account for such facts. The hypothesis of the continuity of the germplasm, so strenuously upheld by Weissmann, received particular attention on account of the importance of the corollary deducible from it which affirms the impossibility of characters acquired during the life of the individual being transmitted. Mr. Bennett remarked that a striking divergence of opinion existed on this point among the leading workers in the different fields of biology. He proceeded to trace the history of the human jaws so far as it is known, commencing by referring, for purposes of comparison, to the chief peculiarities of the simian type of jaw, and then describing the various interesting discoveries of human remains of palæolithic and neolithic periods, including jaws and teeth, which have been made at different times. A further comparison with the different types found among the lower races at the present day showed how gradual had been the diminution in the degree of prognathism and the dental suppression by which had been evolved the jaw found in the modern examples of the Aryan races. The explanations supposed to account for these changes were discussed, and while accepting as possible factors in the process such influences as sexual selection and the mixture of races Mr. Bennett argued that these were probably incapable of accounting for all the facts which presented themselves. He pointed out the difficulty of believing that disuse could have any effects on calcified tooth structure in causing a modification which might be perpetuated by inheritance, except on the supposition that diminished nutrition in the smaller jaw occasioned gradual abortion of the wisdom tooth in the cramped space available for it. With regard to the jaw itself, the inherent probability of diminution owing to the accumulated inherited effects of disuse was greater. Mr. Bennett devoted considerable attention to the views expressed by Dr. J. Sim Wallace in some recent articles on the etiology of dental caries. He was unable to support Dr. Wallace's theories (1) that the size of the jaw was the direct expression of the size of the tongue and that the latter frequently did not attain its full development owing to the removal of the fibrous portions of the food-stuffs by civilised peoples; and (2) that the diminution in the size of teeth was occasioned by decreased liability to caries incident to these variations and the consequent survival of the individual. Mr. Bennett brought many arguments to bear in opposition to most of Dr. Wallace's contentions and went on to point out how the theory of "regression towards mediocrity" propounded by Galton and supported by Russel Wallace might be invoked to explain most of the facts of degeneration of the teeth and jaws without assuming as a fact the inheritance of acquired characters; but in concluding this part of his paper he expressed the view that a verdict of non-proven was the only possible one at present. The second part of the paper was concerned with the researches of Dr. Black on the strength, density, and percentage of lime-salts in human teeth, and Mr. Leon Williams's demonstrations of the earliest stages of dental caries and the bearing of these investigations on current views. Mr. Bennett deprecated the tendency of many odontologists to accept the inference that the variability of susceptibility to dental caries must of necessity be sought for outside the teeth themselves, and he showed that, even if Dr. Black's observations were accepted in their entirety, such a conclusion was not the logical outcome. While believing that the ever-varying condition of the oral fluids might be a most fruitful subject for investigation, yet he urged the view that there might be, and probably were, physical and molecular differences between teeth the chemical composition of which was shown to be as nearly as possible identical, and that associated with such differences there might be correlated a dissimilar degree of susceptibility to the micro-organisms of dental caries.

REMARKABLE EXPLOSIONS AT MANCHESTER.

ON May 3rd a series of violent explosions took place in Sandal-street, Bradford-road, Manchester. The district contains a number of chemical works. An inquiry will no doubt be held as to the cause of the explosions, but it is said that "quantities of the noxious vapours generated in the processes carried on in some of these works find their way into the sewers, and it is to this cause that the explosion is at present attributed." A little before 3 P.M. the ironwork of the manhole at the foot of Sandal-street and the heavy stone setts surrounding it were suddenly blown into the air with a loud report. This was succeeded by a similar explosion at the next manhole, followed quickly by others, till all the manholes covering a distance of nearly 400 yards had been destroyed. In two adjoining thoroughfares manholes were blown up, "and in each case eye-witnesses state that the explosion was followed by a flame of considerable height." A very offensive odour accompanied the explosions. Although this part of the neighbourhood is thickly populated no one was hurt owing to the children being in school and their parents in the mills and works. The operations carried on at the various works are many and unsavoury. They include tar-distilling, the manufacture of sulphuric acid and sulphate of ammonia, benzol rectifying, the manufacture of paint and varnish, the treatment of gas products, oil-distilling, and other similar manufactures. The residents have often complained of nuisances. It is said that sulphuretted hydrogen has been found to be given off in the sewers. The inspectors have discovered, it is stated, that spent acid from benzol was being put into the sewers, which coming into contact with spent ammonia liquor gave rise to an evolution of sulphuretted hydrogen. In May, 1898, the medical officer of health, with an inspector, found a quantity of naphthalene in two of the manholes. Creasote has also got in from a tank having been allowed to run over. People have complained that the noxious vapours have got into their houses from the sewers, and on one occasion there was an explosion in a kitchen, when the flooring was torn up and much damage was done. The dwellers in this evil-smelling and dangerous neighbourhood look on this last exploit of the imprisoned gases as being perhaps a blessing in disguise, and hope that at last definite steps will be taken by the authorities "to remedy the dangerous conditions in which they live and of which they have long complained."

THE FESTIVAL DINNER OF THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

ON Wednesday next, May 22nd, the festival dinner of the Medical Graduates' College and Polyclinic will be held at the Hotel Cecil. No pains have been spared to make the occasion a successful and even a remarkable one. Mr. A. J. Balfour in the chair will be supported by some 400 gentlemen interested in the welfare of the institution, and among the speakers will be the new Bishop of London, Sir William Broadbent (the President of the Polyclinic), Lord Strathcona, and the Duke of Marlborough. The efforts of these speakers will be openly directed towards obtaining for the Polyclinic a large sum of money and as the orators will have at the table with them some of the richest and most open-handed citizens of the empire we may feel confident that a substantial result will be obtained. The Polyclinic, as we have said on previous occasions, fills a gap in the medical education of this country. If it had a substantial endowment its uses as a central school for post-graduate students would be so immediately recognised that the students would themselves by their numbers supply the income necessary to carry on the work. That, at least, is our belief and that of the promoters. But in spite of the notable generosity of not a few lovers of science the institution has never been placed upon a substantial pecuniary basis. We should be glad if the festival dinner should prove a turning point in its fortunes which have hitherto not been proportional to its merits or to the labours bestowed upon its working.

UNILATERAL CLUBBING OF THE FINGERS.

AT the meeting of the Société Médicale des Hôpitaux of Paris on March 22nd Dr. Béclère described a case in which the curious condition of clubbing of the fingers of only one hand was present. The left hand was normal; the right had the appearance shown in the third stage of pulmonary tuberculosis; the terminal phalanges were much enlarged and the nails were convex longitudinally as well as transversely. Radiographs showed that this enlargement was confined to the soft parts and that the bones were not affected—the usual condition in clubbed fingers. The patient was a man, aged 65 years, who had a pulsatile swelling of the size of a large egg in the right subclavicular region—no doubt a subclavian aneurysm. He could not state the time of the onset of the swelling, but he was very definite as to that of the deformity of the fingers; it began a year previously, a little after the appearance of severe pains in the right shoulder which radiated into the neck and hand. At this time, according to the patient, the hand was swollen and violaceous and the subclavicular region more voluminous than when he came under observation. Dr. Béclère thought that the subclavian artery, and probably vein, had been the seat of acute inflammation which led to permanent narrowing of the latter. This hypothesis was confirmed by the fact that while at rest the hands were of the same colour, but on exertion the right became slightly cyanosed. The right radial pulse was only a very little weaker than the left. Dr. Béclère showed that the pathogenesis of this unilateral clubbing of the fingers was comparable to that present in congenital cyanosis due to stenosis of the pulmonary artery. In the latter condition the vessel which carries all the blood from the tissues of the body to the lungs is narrowed. As a consequence of the prolonged retention of substances to be eliminated by the lungs, principally CO_2, a chemical modification of the plasma which bathes the tissues of the periphery is produced. In the present case the obstruction to the venous circulation was local instead of general and therefore produced a local result. Dr. Béclère further suggested that in a similar manner the clubbing of the fingers in pulmonary diseases—phthisis, sclerosis of the lungs, and pleural effusion—is due to the narrowing or obliteration of some of the divisions of the pulmonary artery, which produces the same mechanical effect as narrowing of the artery itself.

LEGISLATION ON PENNY ICES: A GOOD EXAMPLE.

THE corporation of Brighton has presented a measure which has just been accepted by a committee of the House of Commons. Though this is a matter of local legislation there is a clause which might with great advantage be embodied in the sanitary Acts that govern the entire kingdom. The Bill proposes to inflict a penalty of 40*s*. on any manufacturer or dealer in "ice-cream, hokey-pokey, or other similar commodity" who stores such articles in any room or cellar in which there is an opening to a drain or who, in the manufacture, sale, or storage of ice-creams, &c., does anything likely to expose them to infection or contamination. Further, it is provided that the corporation shall keep a register of makers and dealers in wares like ice-cream, and that any unregistered person who shall deal in these articles within the borough will render himself liable to a penalty of £5 and a daily penalty of 40*s*. For more than 20 years we have insisted that some such measure was necessary. We have described the homes of some of the Italian itinerant vendors, organ-grinders, and penny-ice men; we have shown how the various constituents are left exposed in small back-yards by the side of overflowing dust-bins and closets of unspeakable foulness. That bacteria may accompany the dust blown over the surface of the milk is obvious, and thus are the delicacies of the poor readily contaminated. That an industry carried out under such conditions should be qualified as an unwholesome industry is but natural, and it would be a farce to talk of controlling unwholesome industries if this were not included in the list. On the other hand, there is no reason why a thoroughly wholesome and good ice should not be provided for the modest sum of 1*d*., particularly if it is sold from a barrow—that is to say, if the cost of production is not weighed down by the expense of keeping a shop. Still, the question arises as to where these ices are to be made. The street-vendors are by poverty driven to live in premises altogether unsuited for the storing and the production of such articles as ices. Where, then, are the ices to be manufactured? We would suggest that some arrangement might possibly be made with a model dairy or that special premises should be provided on the outskirts of the town where the purveyors could go in the morning, purchase the milk and eggs, make the ices on the spot, and in the evening return to these premises and there store their carts. For these facilities they could be charged a small rent. It would not then so much matter where they lived and slept. If all the ices were made and stored at one or two suitably constructed depôts the industry would be under thorough sanitary control. The poor might then still continue to enjoy their penny ices, the vendors might still hope to earn a livelihood by producing these modest luxuries, and parents would no longer be harrassed by the fear that their children ran the risk of being poisoned by the penny-ice man.

THE CORONERSHIP OF THE CITY OF LONDON.

THE medical men at present offering themselves to the Court of Common Council as candidates for the coronership of the City of London are Mr. J. S. E. Cotman, Dr. Major Greenwood, Dr. Bernard O'Connor, and Dr. F. J. Waldo. Mr. Cotman is a member of the London County Council but has no legal qualification. Dr. Greenwood is the medical officer to the General Post Office and a barrister. Dr. O'Connor is also a barrister. Dr. Waldo, a barrister and medical officer of health of the Inner and Middle Temples, was lately medical officer of health of Southwark, where he did vigorous and fearless work for the public. He was runner-up to Dr. Collingridge for the appointment of medical officer of health to the City of London. We have also seen it announced that Dr. W. R. Smith, medical officer of the London School Board, will offer himself for election to the vacant post.

LEUCOCYTOSIS IN TYPHOID PERFORATION.

THE importance of the study of the symptoms of perforation in typhoid fever with a view to early operation has recently been brought before the profession by Professor Osler.[1] One of the symptoms of perforation is leucocytosis, but its value yet remains to be appraised. In the *Boston Medical and Surgical Journal* of April 18th an important paper on this subject based on observations made in the Montreal General and Royal Victoria Hospitals has been published by Mr. Colin K. Russell. Leucocytosis must not be accepted off-hand as proof positive of perforation even when perforation has been previously suspected, for other conditions resembling it may produce leucocytosis. Conversely, in perforation the number of leucocytes in the blood may be diminished. In 37 examinations of the blood in uncomplicated cases of typhoid fever the leucocytes varied between 2000 and 12,000 per cubic millimetre, the average being about 6500. To obtain as uniform results as possible the counting was done at times remote from digestive periods. The following case, in which the signs of perforation were otherwise doubtful, shows the value of leucocytosis. A boy, aged seven years, on the tenth day of an ordinary attack of typhoid fever, complained of gradually increasing pain in the abdomen, especially in the right lower quadrant. There was no alteration in the pulse or temperature or rigidity or distension of the abdomen which showed only slight general tenderness. Vomiting occurred once. Four different examinations of the blood showed an average of 28,000 leucocytes per cubic millimetre. A few hours later there was thought to be slightly increased rigidity of the abdomen. Laparotomy showed a perforation near the mesenteric attachment of the ileum which was sutured. Recovery followed. In another case of perforation leucocytosis was absent. On the sixteenth day of the disease there were 6100 leucocytes per cubic millimetre. Four days later the classical signs of perforation suddenly developed, but the blood-count showed only 4800 leucocytes per cubic millimetre. The perforation was sutured, as also were six other ulcers which had nearly perforated, but the patient succumbed. In a third case pain suddenly appeared in the abdomen on the fourteenth day, chiefly in the left lower quadrant. The pain gradually increased and within 32 hours marked rigidity was present. The leucocyte counts gave an average of 14,500 per cubic millimetre. But laparotomy revealed neither perforation nor peritonitis. Recovery followed. In a number of other complications of typhoid fever leucocytosis was found. In one patient in whom only simple bronchitis could be discovered there were 20,000 leucocytes per cubic millimetre, in a case of cholecystitis 13,000, and in one of general sepsis 13,000. Mr. Russell draws the following conclusions: (1) in perforation leucocytosis is the rule, but it varies widely; (2) it usually appears early, but may not be marked until general peritonitis and collapse have supervened; (3) it may be absent in marked perforation and peritonitis—in fact, the number of leucocytes may be below normal; (4) typical signs of perforation and leucocytosis may be present without any such complication; and (5) if abdominal pain and tenderness come on suddenly and if in the absence of other complications there is distinct leucocytosis, even without other signs of perforation, operation is justifiable and may be advisable.

[1] THE LANCET, Feb. 9th, 1901, p. 353.

A "TUBE" DANGER.

It is obvious that every possible precaution should be taken to prevent any alarms on the electric underground railways, because if a panic arises escape from any seeming danger is well-nigh impossible. A case in point occurred in Paris last week. A stack of timber adjoining one of the stations of the underground electric railway by some means or other caught fire and a train emerging from the tunnel plunged into the flames. The engine-driver, however, was smart enough to let his train go on through the station instead of stopping it, with the result at any rate that the passengers escaped the dangers of fire. But the tunnel on the other side was full of smoke, a panic arose, and several persons were badly injured in the scramble to get out of the train and the tunnel. This accident emphasises, as we have said, the necessity of keeping the line of route quite free from the possibility of dangers of this incidental sort. Apart from the risk of receiving a powerful current along the track there is the risk also of being deprived of air unless the ventilation is very efficient. In the accident at Paris, however, it is probable that the efficiency of the ventilation or the effect of the heat-currents served to draw both flame and smoke into the tunnel. By the good sense of the guard the passengers were warned to keep off the electric cable—a warning which probably made the whole occurrence less disastrous than it might have been.

CONGENITAL MALPOSITION OF THE INTESTINES.

The following case, which is published in the *Intercolonial Medical Journal of Australasia* by Mr. R. Hamilton Russell, is of interest both on account of the rarity of the pathological condition and the peculiarity of the symptoms. A boy, aged 11 years, was admitted to hospital. When seen on the following morning he was found in bed in the "knee-elbow position" and moaning with abdominal pain. The eyes were sunken, the skin was dry and scurfy, and the body was wasted. With difficulty he was induced to lie on his back, when the abdomen was found to be retracted. Examination of the abdomen seemed to bring on an attack of colicky pain which caused him to resume the knee-elbow position. He then commenced to vomit bile stained fluid. The illness had commenced a fortnight previously with sudden abdominal pain and vomiting which continued more or less up to the time of admission. During this time the bowels acted only with the aid of enemata. At the age of three years an attack similar to the present one occurred. After six years of immunity another occurred. The practitioner who attended him said there was great difficulty in examining him on account of his "assuming a position like that figured to show the postural treatment of prolapsed funis." A month or two later another attack occurred which lasted three weeks. The mother "was sure the child was wrong inside." "His appetite had never been like that of other children; he often ate ravenously and craved for extraordinary articles." Some form of incomplete intestinal obstruction was diagnosed. As the child was seriously depressed and as he had recovered from similar attacks it was decided to postpone operation. An enema brought away a fairly copious motion. On the following morning he became collapsed and died. The necropsy showed deep congestion of the ascending and first part of the transverse colon and of the whole of the small intestine. The transverse colon was obstructed by the passage over it of a dense band. The exact anatomical condition could not be made out until the whole of the intestines had been removed from the body. The band was then found to be the first part of the jejunum together with the whole thickness of the mesentery, which took a sharp turn upwards to the right, passed in front of the transverse colon, then arched over and descended behind it. The entire small intestine was, so to speak, conveyed behind the ascending colon which was dilated and completely enveloped in peritoneum. This remarkable malposition of the intestines appears to have been of congenital origin and connected with the developmental migration of the cæcum. Mr. Russell suggests that the constant assumption by the child of the knee-elbow position was due to relief afforded from the pain which no doubt was chiefly caused by dragging upon the nerves of the mesentery. Similar cases of malposition of the intestines are rare. In The Lancet a case of congenital malposition which terminated in fatal obstruction was published by Dr. Florence Boyd.[1] The patient was a woman, aged 39 years, who was subject to attacks of abdominal trouble characterised by distension, tenderness, and visible peristalsis. Mr. Russell concludes that in his case an operation would have been futile, for it would have been impossible to have made out the condition present or to have remedied it by any feasible procedure.

"A LITTLE LEARNING."

We have often had opportunities to notice the peculiarly thorough ignorance of matters in the least medical which is exhibited by writers in the general press. It is quite right, of course, that these gentlemen, and the rest of the non-medical public for that matter, should not through mere idle curiosity dabble in medicine or play about hospital wards. It is far better for them to regard medicine as a necessary evil and to keep away from all that concerns it, relying on their medical advisers for instruction when necessary. This laudable ignorance of medical matters, though, should be reckoned with by an editor when any work is to be criticised that touches at all on this unvisited province. By the exercise of a little discrimination in this way we should be spared the quaint exposition of ignorance made by a contemporary whose critic talks of a "corner of the dissecting-room heavy with the smell of ether." The dissecting-room in this gentleman's mind—as in that of the great lady who was the foundation of one of Du Maurier's pictures in *Punch* where a young couple shudder at the idea of taking a house near a West-end hospital because of the "shrieks from the dissecting-room"—is evidently synonymous with the operating theatre. We can confidently assure him that the two places are quite separate and that though the latter may be "heavy with the smell of ether" the odour pervading the former is more commonly that due to various brands of tobacco.

CHARING CROSS HOSPITAL: THE CHERE REINE LODGE OF FREEMASONS.

All Charing Cross Hospital men who are Freemasons will be pleased to hear that a warrant has been granted by Grand Lodge to found a lodge in connexion with Charing Cross Hospital. This lodge, the Chère Reine, No. 2853, will be consecrated on June 7th at the Hotel Cecil. Brethren who would like tickets for the ceremony or who desire to become joining members of the lodge are requested to communicate at once with Bro. Carter Braine, 67, Wimpole-street, W.

SUGGESTION AND HYPNOTISM IN THEIR RELATION TO JURISPRUDENCE.

Dr. Baron von Schrenck-Notzing of Munich contributes to the March number of the *Medico-Legal Journal* a valuable paper on the above subject based largely upon his own unrivalled experience in this field of psychological medicine. Criminal acts may be committed by hypnotised subjects while in the hypnotic stage, or by subjects in the state of wakefulness who had been previously hypnotised and influenced by suggestion to criminal acts. Moreover, the hypnotised subject may be abused or criminally wronged by the hypnotiser. Among criminal acts belonging to the last category attempts upon decency and morality occupy the first place. Such cases have been reported by Bellanger, Laurent, Ladame, Brouardel, Krafft-Ebing, and Schrenck-Notzing himself. "In all these cases there was always proved the undoubted existence of hypnotic sleep ..... for in order to carry out these crimes recourse had to be taken to the most profound hypnotisation, whereby the subject was deprived of the faculty of resistance or had become an automaton of the hypnotiser, and very often we had to deal with a condition of hysterical sleep or lethargy." Natural modesty and good bringing-up offer an undoubted resistance to sexual attempts and cannot be overcome by the help of a few opposite suggestions, whereas sensual temperaments are more easily seduced. There are all shades of difference between such resistance to criminal suggestion and absolute obedience. Two instances of sexual crimes committed under hypnotic suggestion came recently under notice and in a third instance also observed by Schrenck-Notzing a theft was committed under the influence of hypnotic action. Sexual attempts and theft constitute the majority of cases, but instances of abortion and of substitution of infants with the aid of hypnosis are not unknown. The suggestion of sickness to escape from military service is rare. Injury to health, especially mentally and morally, may be the result of hypnosis by laymen, professional magnetisers, and public performers who claim to work cures in this way. The dangers arising from taking part in magnetic *séances* and exhibitions of a semi-public character are not insignificant. After re-affirming the difficulty of inducing normal individuals of good *morale* and training to participate in criminal acts, even when induced thereto by hypnosis, Schrenck-Notzing refers to the greater importance of hypnotic suggestion in the condition of wakefulness. He quotes the case of the woman Sauter who was tried before the Court of Assizes at Munich in 1899. She was charged with the attempt to murder and with instigating several persons to murder. She was an ignorant woman under the influence of soothsayers and absolutely acquiesced in and attempted to carry out their suggestions. A full report of the case by Schrenck-Notzing was laid before the court and the woman was acquitted. It is pointed out that criminal suggestions in the waking state may have dangerous influence upon certain classes of persons—e g., infants, hysterical persons, and persons with an easily excited imagination. A case is reported of a nurse who suffered from a mania of destructiveness but who was unscrupulous enough to suggest to her charge, a little girl aged seven years, that the latter should confess to the misdeeds. During nine months the little girl voluntarily made herself the scapegoat, confessed to being the wrongdoer, and voluntarily bore every punishment without ever betraying her nurse. Persons who commit crimes suggested to them are rarely of perfectly sane mind. But the more a person is without energy or strength of will or is the subject of congenital moral defect the more potent does suggestion become. Certain nervous ailments, such as hysteria, neurasthenia, epilepsy, and certain critical epochs of life, as puberty, and the menopause, render individuals more prone to suggestion for good or evil

UNIVERSITY OF LONDON: THE STANDING COMMITTEE OF THE FACULTY OF MEDICINE.

A meeting of the members of Convocation of the University of London was held at the University's new building at South Kensington on Tuesday, May 14th, at 5 P.M. Sir E H Busk had been duly nominated for the appointment of chairman and Mr. H. E. Allen as clerk. Several alterations in the standing orders were proposed. The members of the standing committees were also elected. There were nine vacancies in the Faculty of Medicine and the little interest taken by the medical graduates in the proceedings of convocation under the new statutes is shown by the fact that four of the nine persons who have been duly nominated are connected with one medical school—viz , the London School of Medicine for Women.

A general meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at 11, Chandos-street, Cavendish-square, W., on Thursday, May 23rd, at 3 P M , under the presidency of Dr. Fletcher Beach, when Dr. Charles Mercier will read a paper on "Punishment," and Dr R. P. Smith will deal with "A Case of Epileptic Homicide." Dr. D. G. Thomson will take for his subject "Senile Insanity." At two o'clock a number of slides showing the condition of nerve-cells and association fibres in cases of idiocy and juvenile general paralysis will be shown, and in the evening the members of the association will dine together at the Café Royal, Regent-street, W.

The annual dinner of the British Balneological and Climatological Society will be held at Limmer's Hotel on Friday, May 31st, at 6 30 P.M., under the presidency of Dr. Frederic Bagshawe. Communications should be addressed to one of the honorary secretaries, Dr. S. Sunderland, 11, Cavendish-place, W., or Mr. Shirley Jones, Droitwich. After the dinner the annual conversazione will be held at 20, Hanover-square, when Dr. I. Burney Yeo will give an address on Hepatic Inadequacy.

The annual meeting of the Association of Asylum Workers will be held at the Medical Society's House, 11, Chandos-street, Cavendish-square, W., on Friday, May 24th, at 4 P.M , Sir James Crichton-Browne, M.D. Edin , LL D., F.R.S. (President of the association), in the chair. All interested in asylum work and workers are cordially invited to attend.

Amongst the Australian Commonwealth honours recently bestowed at Melbourne by H.R H. the Duke of Cornwall we are glad to notice the name of the medical Mayor of Sydney. We congratulate Sir James Graham, M A., M.D. (gold medal) Edin., M.B. Sydney (*ad eundem*), on being created a Knight Bachelor.

THE opening lecture of the summer session at Brompton Hospital for Consumption and Diseases of the Chest will be delivered by Dr. J. Mitchell Bruce on Wednesday, May 22nd, at 4 P.M. Subject: "On the Diagnosis, Prognosis, and Treatment of Quiescent Tuberculosis."

SIR WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., has been elected a Foreign Associate Fellow of the College of Physicians of Philadelphia, the oldest medical body in America, having been founded by Benjamin Rush and other distinguished men in 1787.

AT the meeting of the University Court held in Carmarthen on May 10th Dr. Isambard Owen was for the seventh year in succession elected Senior Deputy Chancellor of the University of Wales.

THE Metropolitan Counties Branch of the British Medical Association will hold a conversazione in the Natural History Museum, South Kensington, at 8.30 P.M., on Wednesday, June 12th.

AN extra meeting of the Pathological Society of London will be held at Oxford on Saturday, July 6th, upon the invitation of Sir John Burdon Sanderson and Dr. J. Ritchie.

THE newly-appointed Bishop of Oxford, the Very Rev. Francis Paget, D.D., Dean of Christ Church, is the second son of the late Sir James Paget, Bart., F.R.C.S.

THE King has nominated Sir John Williams, Bart., M.D. Lond., to be a member of the General Medical Council for a term of five years.

LIEUTENANT-COLONEL BABTIE, V.C., C.M.G., has been temporarily appointed Assistant Director of the Army Medical Service.

DR. S. WEST has been appointed Joint Lecturer on Medicine at St. Bartholomew's Hospital, vice Sir Dyce Duckworth, resigned.

MEDICAL MEN AND THE WORKMEN'S COMPENSATION ACTS.

I.

THE Workmen's Compensation Act of 1897 considerably increased the liability of the employer to his workman when the latter was accidentally injured in those trades to which it applies, and imposed duties upon medical practitioners in connexion with the assessment of the workman's injuries beyond those naturally arising out of the ordinary summons to assist the injured in his home or the hospital.

The scope of this Act has now been enormously widened by a recent statute which extends its benefits to the agricultural labourer, stating that it "shall apply to the employment of workmen in agriculture by any employer who habitually employs one or more workmen in such employment," while, to quote further from the new Act, "where any workman is employed by the same employer mainly in agricultural but partly or occasionally in other work, this Act shall apply also to the employment of the workmen in such other work," and "the expression 'agriculture' includes horticulture, forestry, and the use of land for any purpose of husbandry, inclusive of the keeping or breeding of live stock, poultry, or bees and the growth of fruit and vegetables." From these definitions it will be seen that a workman in agriculture within the meaning of the Workmen's Compensation Acts is a member of a very large class indeed, and that not only the labourer who follows the plough will be entitled to compensation, but, if we may suggest an instance, the gardener who is also employed to drive and who meets with a carriage accident when engaged in the latter occupation. The country labourer does not meet with many accidents which do not arise "out of and in the course of his employment," and it will readily be seen that the majority of accidents occurring to him for which a medical man is called in may become the subject of claims for compensation. The new statute which protects the workman in agriculture comes into force on July 1st next, and it may be of interest to the enlarged class of medical men who will now be called upon from time to time to consider certain provisions of the Workmen's Compensation Act of 1897 if we set out and comment briefly on those which most intimately concern the medical profession. Until the Act of 1897 was passed the medical man, as a rule, became concerned with an action arising out of a workman's accident either because he had attended the injured man or because by his consent he had examined him on behalf of the employer. Under the Act we are discussing the employer to whom notice of an accident has been given by an injured workman can call upon the workman to submit himself to a medical man selected and paid by the employer, and further, after compensation has been awarded and while weekly payments are being made to the workman, the employer, or any person by whom the employer is entitled to be indemnified—as, for example, an insurer—can call upon the workman to submit himself to further examination either to a medical practitioner chosen and paid by the employer, or should the workman object to the medical practitioner or to the certificate given by him, then he may submit himself to one of the medical practitioners appointed for the purpose of the Act as medical referees. These are to be appointed by the Secretary of State and their expenses are to be paid out of moneys to be provided by Parliament. They have duties beyond those already indicated, for they may be called in when required by an arbitrator under the Act to report upon questions arising in the course of the arbitration.

Many very difficult questions of law have arisen under the Workmen's Compensation Acts, as they have under the Employers' Liability Act. We need not consider these at great length, but we shall indicate the scope of the Acts generally, as the medical man will be called in on many occasions by uneducated persons who in many cases will not be able to afford legal assistance. We have no desire to constitute the medical practitioner legal adviser to these, but he should be aware of the legal position of his patients so far as it affects his own and so far as it is readily ascertainable by him.

Before 1880 the workman injured in the course of his employment had a right to compensation by his employer in very few cases indeed. Where the employer caused by his own negligence the injury of his workmen he might be compelled by an action at common law to compensate him, but he owed him no compensation, such as he would to a stranger, if the negligence of a fellow-worker of the injured man caused the mishap, and there were defences open to the employer with regard to the workman's knowledge of the dangers of his employment and other matters that we need not go into. By the Employers' Liability Act of 1880 the employer was made liable in certain cases which did not cover all accidents, or apply to all employments, such as where the accident results from a defect in the condition of ways, works, machinery, or plant, or from the negligence of a person appointed by the employer to superintend work, or of any foreman whose order, obeyed by the workman, has resulted in his injury. Under the Workmen's Compensation Act, in addition to his previous liability at common law or under the Employers' Liability Act, the employer is liable if in any employment to which the Act applies "personal injury by accident arising out of and in course of the employment is caused to a workman," unless the accident is caused by the "serious and wilful misconduct" of the workman, and with the following further proviso, which directly involves the evidence of the medical man, that "the employer shall not be liable under this Act in respect of any injury which does not disable the workman for a period of at least two weeks from earning full wages at the work at which he was employed"—that is to say, before the workman can claim compensation there must be a period of 14 days, not counting the day on which the accident happens or the day on which the workman returns to full work, during which he is disabled, and consequently slight injuries are not subjects for compensation. We need hardly point out that the question of the workman's inability to earn full wages during a precisely defined period is one which must largely depend on medical evidence, and that this provision of the law may well be borne in mind by the medical man while he is treating an accident that is otherwise within the Act.

Glancing at the conclusion of the Workmen's Compensation Act of 1897 before going further we find that it applies to "employment in or about a railway, factory, mine, quarry, or engineering work, or in or about any building which exceeds 30 feet in height, and is either being constructed or repaired by means of a scaffolding, or being demolished, or on which machinery driven by steam, water, or other mechanical power is being used for the purpose of the construction, repair, or demolition thereof." If to this definition is added that of the workman in agriculture from the Act of 1900 given above, the medical practitioner will have a general idea of the class of case in which his services may be required under these two statutes. He need not trouble himself with the legal combats that have raged over the construction of almost every phrase which we have quoted that purports to limit the accidents for which compensation is to be made, but he may remember that some of the most important actions arise where death has resulted and where there are dependants to be compensated, and that in these especially medical testimony may be of some effect in determining precisely the manner in which the accident occurred, and, further, that the question whether there was "serious and wilful misconduct" on the part of the workman is one of vital importance to his claim, or that of his dependants, for compensation. We need hardly say with reference to this class of evidence that the less a medical witness allows himself to be drawn into formulating speculative theories and the more strictly he confines himself to straightforward statements of fact, the better his evidence will stand criticism by a hostile advocate.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 9th, the President, Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., being in the chair.

Mr. Priestley Smith and Major Ronald Ross were introduced and after signing the by-laws and making the required declaration they were admitted Fellows of the College.

Mr. William McAdam Eccles was introduced and the President handed to him the Jacksonian Prize, together with a document declaratory of the award.

On the recommendation of the Library Committee it was resolved to provide an additional store-room for books in the basement of the College.

The Committee on the annual report of the Council presented a report on the following letter from Mr. George Brown and Dr. Danford Thomas.

To the President and Members of the Council of the Royal College of Surgeons of England.

GENTLEMEN,—In [illegible] quest of your Council as [illegible] st, we beg to submit the [illegible] opinion the Medical Acts [illegible]

1. Alteration in the [illegible] Medical Council to [illegible] ities and Medical [illegible] ical graduates and [illegible] be obtained only [illegible] Conjoint Board as [illegible] for each division of the kingdom. All the medical corporations in each division to be represented on the respective Divisional Conjoint Board.

3. That in lieu of the present method of registration there shall be an annual registration, the fee for which shall not exceed twenty shillings.

4. That no unregistered person shall practise medicine or surgery or any branch thereof for gain, or use any medical or surgical title or titles calculated to lead the public to believe that the person using such title or titles is a [illegible]

5. The [illegible] branch thereof by any [illegible] olly or in part unregis [illegible]

In addition to the above suggested reforms of the Medical Acts, we would draw attention to the desirability of the Council of the College, in the public interest, takings steps with a view to an amendment of the law relating to the sale of drugs so as to compel the vendors of all patent medicines and proprietary nostrums to state on the package or bottle containing the alleged remedy the exact composition.

In earnestly recommending the serious attention of the Council to the urgent necessity that exists for the above-mentioned reforms, we desire to thank the Council for the opportunity thus afforded for placing these views before them.

And we have the honour to remain,

Your obedient servants,

GEORGE BROWN.

GEO. DANFORD THOMAS.

The Council passed the following resolution:—

The Council are not prepared to promote the alterations suggested in paragraphs 1, 2, and 3. With regard to paragraph 4 the Council approve the principle that no unregistered person should be allowed to practise medicine or surgery for gain, and if the General Medical Council should deem it expedient to apply for an alteration of the Medical Acts to that effect the Council would support their action. Regarding paragraph 5 the Council deem it inexpedient at the present time [illegible] medicines and [illegible] package or b[illegible] tion the Coun[illegible] to initiate proposals for the amendment of the law relating to the sale of drugs.

Mr. R. J. Godlee was appointed a delegate from the College to the Congress on Tuberculosis to be held in London in July next.

The President was re-appointed the representative of the College on the Council of the Jenner Institute of Preventive Medicine.

The report of the Committee on the proposed changes in the regulations for the Licence in dental surgery was received, and it was referred to the Dental Board of Examiners to revise the regulations. The chief alterations will be that at the final examination the marks in anatomy and physiology and in surgery and pathology will be independent of those in dental anatomy and surgery, and that the candidate may be rejected in one part of the examination without being rejected in the other; and further, that candidates will be permitted to take the general anatomical and surgical and the dental parts of the examination separately. Moreover, courses of lectures on dental bacteriology and dental materia medica will be added to the curriculum.

Mr. J. HARDIE moved that it be referred to the Committee of Management to consider and to report upon the desirability of it being required of candidates for the Membership of the College to furnish certificates of having been taught the administration of anæsthetics. The subject was so referred.

The College accepted with thanks a portrait by Mr. T. B. Kennington of the late Dr. Richard Neale, presented by the Neale Testimonial Fund Committee.

Sir Frederick Treves, chairman of the Library Committee, presented to the College on behalf of Sir William Mac Cormac, the President, an album containing autograph photographs of all the celebrities attending the International Medical Congress held in London in 1881. These photographs had been collected by Sir William Mac Cormac, the honorary secretary-general to the Congress.

The thanks of the Council were voted for the gift.

The next meeting of the Council will be on June 20th.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

A MEETING of the General Council of this fund was held on May 10th, at the residence of the Duke of Fife, 15, Portman-square, W., his Grace occupying the chair on behalf of H.R.H. the Duke of Cornwall and York.

The DUKE of FIFE announced the resignation of the presidency of the fund by the King, who would become its patron, and the acceptance of the presidency of the Fund by the Duke of Cornwall and York.

Mr. H. O. SMITH read the report of the General Council for the year ending 1900 which recorded an increase of £3000 in the total receipts for the year. Excluding the initial start in the Jubilee year the figures showed continuous progress—viz.: 1898, £39,272; 1899, £48,636; and 1900, £51,649. Although the receipts were only £3000 in excess of the previous year it was felt that the claims of the hospitals justified a larger distribution than before, and it was decided to award to the hospitals and convalescent homes £50,000, as compared with £42,000 in the last year, being an increase of £8000. No appeal was made to the public for 18 months, so as to avoid any clashing with the various war funds, but shortly before the close of the year an appeal was issued. The response to this was somewhat disappointing, but with some special gifts it was only necessary to withdraw from the balance of the funds in hand a sum of £2183 8*s.* 4*d.* in order to make up the distribution of £50,000 The League of Mercy was enabled to contribute £6000 in 1900, as compared with £1000 in the previous year. The expenditure for the year had been £1960, as compared with £1853 in 1899. The report closed by stating that while the work of this Fund was limited to the London hospitals, yet the hospitals themselves were a centre of very wide influence, extending far beyond the limits of London; indeed, to a greater or less extent they affected the wellbeing of the whole Empire, as they supplied no inconsiderable proportion of the medical men whose services were afterwards devoted to all parts of the Empire.

Lord FARQUHAR, in seconding the adoption of the report, said that they hoped that the war which had engaged so much attention and had naturally drawn such large subscriptions from all private people for nearly two years was now coming to an end, and that, therefore, more funds would be available for the excellent cause that they were assembled to support. He referred to the way in which the hospitals had been visited and to the manner in which the Committee had awarded the different sums—a very important matter. It had given general satisfaction.

The Rev. T. BOWMAN STEPHENSON, Sir TREVOR LAWRENCE, Sir HENRY BURDETT, and Mr. J. G. CRAGGS having spoken on the motion it was put to the meeting and was carried unanimously.

On the motion of Lord ROTHSCHILD, seconded by Lord REAY, the accounts and balance-sheet were adopted and passed.

Lord DUNCANNON moved that Mr. A. D. Fripp, F.R.C.S. Eng., and Sir Savile Crossley (both of whom had returned from South Africa) be added to the list of visitors and expressed the hope that the gentlemen who had so kindly acted as visitors last year would continue to undertake this most important duty.

Lord IVEAGH having seconded the motion, various votes of thanks terminated the proceedings.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6419 births and 3635 deaths were registered during the week ending May 11th. The annual rate of mortality in these towns, which had declined from 19·7 to 17·3 per 1000 in the four preceding weeks, further declined last week to 16 5. In London the death-rate was 15 9 per 1000, while it averaged 16 9 in the 32 large provincial towns. The lowest death-rates in these towns were 7 7 in Croydon, 11·6 in Plymouth, 12 7 in Birkenhead, and 13 2 in Gateshead; the highest rates were 19 6 in Hull, 20 4 in Swansea, 20·7 in Manchester, and 22·3 in Brighton. The 3635 deaths in these towns included 381 which were referred to the principal zymotic diseases, against 363 and 394 in the two preceding weeks; of these, 118 resulted from whooping-cough, 90 from measles, 63 from diphtheria, 46 from diarrhœal diseases, 38 from scarlet fever, 25 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Wolverhampton or in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Plymouth, Derby, and Birkenhead, and the highest rates in Portsmouth, Salford, Blackburn, and Sheffield. The greatest mortality from measles occurred in Portsmouth, Bolton, and Gateshead; from whooping-cough in Bristol, Swansea, Birmingham, Burnley, and Newcastle; and from "fever" in Blackburn. The mortality from scarlet fever and that from diarrhœal diseases showed no marked excess in any of the 33 large towns. The 63 deaths from diphtheria included 23 in London, 11 in Sheffield, four in Blackburn, three in Birmingham, three in Leicester, and three in Liverpool. One fatal case of small-pox was registered in London, but not one in any other of the 33 towns; and no small-pox patients remained under treatment in any of the Metropolitan Asylums hospitals on Saturday, May 11th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1913, against 1522 and 1705 on the two preceding Saturdays; 397 new cases were admitted during the week, against 150, 198, and 371 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 374, 286, and 251 in the three preceding weeks, further declined last week to 237, and were 73 below the corrected average. The causes of 35, or 1·0 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Hull, Newcastle, and 16 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·1 to 21·2 per 1000 in the five preceding weeks, further decreased to 19 3 per 1000 during the week ending May 11th, but showed an excess of 2·8 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12·0 in Aberdeen and 15·1 in Perth to 21 6 in Greenock and 22 8 in Dundee. The 606 deaths in these towns included 49 which were referred to whooping-cough, 20 to diarrhœa, 17 to measles, eight to scarlet fever, four to diphtheria, and one to small-pox. In all, 99 deaths resulted from these principal zymotic diseases last week, against 120 and 83 in the two preceding weeks. These 99 deaths were equal to an annual rate of 3 2 per 1000, which was 1·5 per 1000 above the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 62 and 39 in the two preceding weeks, rose again last week to 49, of which 21 occurred in Glasgow, 16 in Edinburgh, six in Dundee, three in Leith, and two in Paisley. The deaths from diarrhœa, which had been 23, 13, and 12 in the three preceding weeks, rose again to 20 last week, and included nine in Glasgow, five in Dundee, and two in Paisley. The fatal cases of measles, which had been 25 and 17 in the two preceding weeks, were again 17 last week, of which six were registered in Edinburgh, six in Leith, and five in Glasgow. The eight deaths from scarlet fever corresponded with the number in each of the two preceding weeks, and included three in Dundee, two in Glasgow, and two in Edinburgh. The fatal cases of small-pox, which had been 10, three, and three in the three preceding weeks, decreased last week to one, which was registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 169 and 125 in the two preceding weeks, further declined last week to 116, but were 25 in excess of the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 35 6 to 26 5 per 1000 in the four preceding weeks, rose again to 27 4 during the week ending May 11th. During the past four weeks the death-rate in the city has averaged 29 7 per 1000, the rates during the same period being 17·1 in London and 23·2 in Edinburgh. The 182 deaths of persons belonging to Dublin registered during the week under notice were six in excess of the number in the preceding week and included 15 which were referred to the principal zymotic diseases, against 10 and 13 in the two preceding weeks; of these, seven resulted from whooping-cough, three from diarrhœa, two from scarlet fever, two from "fever," and one from measles. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death rate during the same period being 1·6 in London and 4 4 in Edinburgh. The fatal cases of whooping-cough, which had been eight and nine in the two preceding weeks, declined again last week to seven. The three deaths from diarrhœa showed a slight excess over the number in the preceding week. The fatal cases of "fever," which had been three, one, and two in the three preceding weeks,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1901.

* Including membranous croup.

were again two last week. The 182 deaths in Dublin last week included 30 of children under one year of age and 48 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were in excess of the numbers recorded in the preceding week. Four inquest cases and two deaths from violence were registered; and 77, or more than two-fifths, of the deaths occurred in public institutions. The causes of 10, or more than five per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 29 cities and boroughs in the county of London. With regard to the notified cases of infectious diseases the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·2 per 1000 of the population, provisionally estimated, on the basis of the unrevised results of the recent Census, to be 4,543,727 persons in the middle of the year. In the three preceding months the rates had been 6·2, 5·7, and 5·2 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, Chelsea, City of Westminster, Stoke Newington, City of London, and Lambeth; while they showed the largest excess in Fulham, St. Marylebone, Southwark, Bermondsey, Deptford, and Woolwich. No case of small-pox was notified in London last month and no small-pox patients were under treatment in any of the Metropolitan Asylums hospitals at the end of April. Scarlet fever was more prevalent last month than in either of the two preceding months; among the various metropolitan boroughs this disease showed the highest proportional prevalence in Hammersmith, Fulham, St. Marylebone, St. Pancras, Southwark, and Lewisham. The Metropolitan Asylums hospitals contained 1491 scarlet fever patients at the end of April, against 1979, 1791, and 1533 at the end of the three preceding months; the weekly admissions averaged 179, against 164, 156, and 142, in the three preceding months. The prevalence of diphtheria showed a marked decline from that recorded in any recent month; the greatest proportional prevalence of this disease occurred in Fulham, Hampstead, Hackney, Stepney, Poplar, and Deptford boroughs. There were 960 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of April, against 1113, 1111, and 1084 at the end of the three preceding months; the weekly admissions averaged 117, against 129, 136, and 134 in the three preceding months. The prevalence of enteric fever last month showed a further decline from that recorded in recent months; among the various metropolitan boroughs this disease was proportionally most prevalent in Stoke Newington, Hackney, Shoreditch, Bermondsey, Deptford, and Woolwich. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 299, 224, and 162 at the end of the three preceding months, had further fallen to 121 at the end of April; the weekly admissions averaged 16, against 32, 25, and 18 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, Bethnal Green, Stepney, and Greenwich. The 36 cases of puerperal fever included two in Islington and two in Greenwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the patients had previously resided. During the four weeks ending April 27th the deaths of 6143 persons belonging to London were registered, equal to an annual rate of 17·6 per 1000, against 17·5, 19·4, and 17·8 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 10·5 in Hampstead, 11·7 in Lewisham, 13·5 in Paddington, 14·0 in Wandsworth, 14·3 in Woolwich, and 14·9 in Kensington; the highest rates were 20·0 in Bethnal Green and in Stepney, 20·1 in Finsbury, 22·1 in Shoreditch, 22·8 in Bermondsey, 23·3 in Southwark, and 25·5 in the City of London. During the four weeks of April 589 deaths were referred to the principal zymotic diseases; of these, 176 resulted from measles, 25 from scarlet fever, 75 from diphtheria, 241 from whooping-cough, 26 from enteric fever, and 46 from diarrhœal diseases. The lowest death-rates last month from these diseases occurred in Chelsea, Stoke Newington, Holborn, Finsbury, City of London, and Woolwich; and the highest rates in Hackney, Southwark, Bermondsey, Battersea, Camberwell, Deptford, and Greenwich. The 176 deaths from measles were 135 below the corrected average; this disease was proportionally most fatal in Hackney, Stepney, Southwark, Bermondsey, Camberwell, Deptford, and Greenwich. The 25 fatal cases of scarlet fever showed a decline of 34 from the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Fulham, St. Pancras, Hackney, Bethnal Green, Bermondsey, and Deptford. The 75 deaths from diphtheria were 69 below the corrected average; this disease was proportionally most fatal in Fulham, St Marylebone, Hackney, City of London, Southwark, and Camberwell. The 241 fatal cases of whooping cough showed a slight decline from the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Kensington, Hammersmith, Fulham, Hampstead, Southwark, and Battersea. The 26 deaths from enteric fever were slightly below the corrected average number; the highest death-rates from this disease occurred in Paddington, Chelsea, Stepney, Poplar, and Southwark. The 46 deaths from diarrhœal diseases showed a slight decline from the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs diarrhœa was proportionally most fatal in Finsbury, Poplar, Battersea, Wandsworth, Deptford, and Woolwich. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during April was nearly 31 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 122 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Stoke Newington, Bethnal Green, Greenwich, Lewisham, and Woolwich; and the highest rates in Kensington, Chelsea, City of Westminster, Shoreditch, Bermondsey, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: Matthew to the *Eclipse*; J. A. Moore and W. W. Pryn to the *President*. Surgeons: G. G. Borrett to the *Minerva*; S. Roach to the *Pembroke*; F. H. A. Clayton to the *Pelorus*; and A. J. Hewitt to the *Eclipse*.

1st Life Guards: Surgeon-Lieutenant-Colonel Horatio R. O. Cross retires on retired pay.

ROYAL ARMY MEDICAL CORPS.

Civil Surgeon R. M. Cowie to be Lieutenant. Major M. Kelly, assistant registrar to the principal medical officer, Netley, is under orders for South Africa. He is to be succeeded at Netley by Captain P. H. Whiston, who has been seconded for service with the Egyptian Army and who is under orders to join his appointment at Netley on May 24th. Captain P. H. Whiston reported his arrival at the Royal Victoria Hospital, Netley, on May 11th. Lieutenant-Colonel W. Rowney succeeds Lieutenant-Colonel Corban in medical charge of the 3rd Station Hospital, and the command of No. 3 Company, R.A.M.C., Aldershot. Captain H. A. Stalkartt assumes medical charge of troops, Station Hospital, &c., Perth. Lieutenants H. R. Bateman and A. D. Jameson have embarked for Egypt.

MILITIA MEDICAL STAFF CORPS.

Stuart Gerald McAllum to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Sussex: Surgeon-Captain H. Habgood to be Surgeon-Major. *Submarine Miners:* The Clyde Division: James Eric Wilson to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the King's (Liverpool Regiment): Thomas Henry Agnew to be Surgeon-Lieutenant. 3rd Volunteer Battalion the Devonshire Regiment: E. R. Tweed to be Surgeon-Lieutenant. 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant E L. Jones to be Surgeon-Captain. 2nd Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment): Surgeon-Lieutenant C. Barlow resigns his commission. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant Colonel W. Mortimer retires, with permission to retain his rank and to wear the uniform of the battalion on retirement; William Cockburn to be Surgeon-Lieutenant. 7th Middlesex (London Scottish): Alexander Howard Pirie to be Surgeon-Lieutenant. 24th Middlesex: Surgeon-Major J. D. Grant resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement.

MENTIONED IN DESPATCHES.

In a despatch received by the Secretary of State for India from Lieutenant-General Sir Alfred Gaselee, K.C B, commanding the British contingent of the China Expeditionary Force, dated headquarters, Peking, Jan 17th, 1901, the following passages occur:—

> The medical department have, I rejoice to say, not been severely tested by this campaign, and ample provision for contingencies [illegible] the [illegible] d an [illegible] the [illegible] been [illegible] the [illegible] oyal [illegible] lical Service.
>
> Colonel J B Bookey, principal medical officer during the first part [illegible] of long service whose [illegible] luties to my satisfaction [illegible] mention for their good [illegible] M.C.; Major H. B Cree, [illegible] ls, I M S; Lieutenant- [illegible] himself to be a particu- [illegible] Spencer, I M S, Lieu- [illegible] W. White, I M S, Major [illegible] W. H Kenrick, I M S [illegible] value to this force of the [illegible] and generously placed at [illegible] by Colonel His Highness [illegible]

SOUTH AFRICAN WAR NOTES.

Surgeon Captain J De B. Griffith of the 3rd Victorian Bushmen left Cape Town on May 9th for Australia in the *Morayshire*.

Major Rickets, R A.M.C., Major J. Osburne, R A.M.C, Lieutenant Forbes Winslow, R.A.M.C., and Civil Surgeons Hunter, Collier, and Davison are on passage home.

Civil Surgeon R Wilbond is reported dangerously ill at Springfontein.

Civil Surgeon Sowden's condition is reported unchanged.

Lieutenant-Colonel J. L Hall, R A.M C., Major S Hickson, R A M.C, Captain R. D. Jephson, R A.M C., and Civil Surgeons S. Wicks, Rust, Corkerton, and H. F. Hine, have been discharged from hospital to duty.

THE DEBATE ON THE NEW ARMY SCHEME

The central point of the recent debate in the House of Commons on Mr. Brodrick's new army organisation scheme really consists in the question: Where are the men to be found to meet its requirements and to fill the new army corps? It does not seem to us that army corps are to be considered as the organisation most suitable for this country because they happen to be the best adapted for the big Continental Powers. The circumstances are quite different in the two cases. But whether the required additions to the strength of the army should go to the formation of the proposed army corps or not does not much matter. It makes but little difference what is to be the military nomenclature or organisation so long as the soldiers are not forthcoming. The outlook for the success of any scheme is not, it must be confessed, very re assuring, for it is not at all clear that the numbers required can be obtained at the present rate of pay. Be that as it may, we want, if possible, to obtain a stronger and, on the whole, a more intelligent type of recruits. Whilst a war fever is present there is no difficulty in getting them, and the question arises whether more cannot be done in time of peace to make the army more attractive than it is. We have already expressed our belief that much could be done in this direction. Our recruiting barracks and depôts in towns need to be greatly improved and not hidden away in back streets. More commissions should be given to the rank and file, for there are many gentlemen and men of education serving in the ranks. The soldier might be given more freedom without endangering military discipline by doing away with all unnecessary drills and many irksome military observances and restraints; and the popularity of the service might be increased by the abolition of hospital stoppages, by the provision of dining-halls, by the laying on of hot water for baths and lavatories in barracks, and by the better lighting of barrack-rooms so as to make them more comfortable and cheerful than at present. But we confess that we do not believe that the provision of barrack-room cubicles (to say nothing of any possible hygienic, military, and moral objections to them) will have any favourable influence on recruiting.

LIEUTENANT COLONEL BABTIE, V.C, C M.G.

Lieutenant-Colonel Babtie has been temporarily appointed Assistant Director of the Army Medical Service. Lieutenant-Colonel Babtie served in the occupation of Crete, 1897-98, as senior medical officer (C M G) He served in South Africa with the Ladysmith relief force and was present at the battle of Colenso, where he earned his V C.

DEATHS IN THE SERVICES

Brigade Surgeon William Beale Wallis, late 74th Highlanders, on May 6th, at Colchester, aged 71 years. He entered the service in 1853, and was promoted surgeon in 1862 and surgeon major in 1873 He retired in 1881.

Correspondence.

"Audi alteram partem."

"THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES."

To the Editors of THE LANCET.

SIRS,—Mr. Brabrook's letter in THE LANCET of April 27th, p. 1232, is evidently written with a view to bringing together the friendly societies and their medical officers. With your permission I would like to draw attention to a few points in the dispute Mr. Brabrook says "the real question is the proper remuneration of the medical man, and the wage-limit is only a part of that question." Proper remuneration is undoubtedly the chief question, and it is equally certain that, as a rule, the present prices are no remuneration whatever. I am glad to see the assertion made that the societies are "neither beggars nor sweaters" and only wish that such a statement could be verified by facts. In too many instances they, on the one hand, beg well-to-do members to join, holding out the free doctor as an inducement, and so, on the other hand, sweat the doctor.

Medical men have always been ready to act charitably in the matter of fees towards those in poor circumstances, and club prices were undoubtedly originally fixed with this question of partial charity towards the poor in view. If the patients of the same class, who are now in many cases earning double the wage and enjoying many luxuries unknown to their fathers, expect that not only they but also really well-to do people are to be treated still at anything like the same rate they surely must be laying themselves open to the charge of sweating

I have frequently heard it admitted by those in good positions that they join the club simply for the doctor—that is to say, that they pay something like 6*d*. per week to the club, 5*d*. of which is supposed to be for sick-pay and 1*d*. or ½*d*. for medical attendance They are too proud or, as they would say, too philanthropic, to accept the sick relief, but they will accept the services of the club doctor. In other words, they are willingly paying 26*s*. per annum for certain work, but only 4*s* 4*d* or 2*s* 2*d* actually reaches the man who does the work, the whole of the rest being absorbed by the middleman, the club. Is not that sweating? Is not that, indeed, sweating in a very pronounced form? Naturally, these are the very men whom the societies beg to join and equally naturally they are the very men whom we wish to keep out. I have known the largest shopkeeper and most extensive property [illegible] g two clubs so as to be at [illegible] with no intention of eve. [illegible] sweating? Club members often assert that they know clubs cannot pay the doctors, but that they act as an advertisement. *Is not that sweating?*

Again, I believe that in some districts members who are debarred from receiving sick-pay on account of their illnesses being the direct result of intoxication or other vice still expect to receive the medical officer's services without extra payment. Is that fair? I am glad to say that in my own district the committees of two clubs have recently corroborated my view of the rules that "debarred from benefit" means debarred from every form of benefit, including the greatest of all—viz., medical attendance. I think Mr. Brabrook must admit that these actual instances must cast the suspicion of sweating upon the friendly societies. With regard to other matters than the actual fee paid it must be conceded that club patients are by no means the easiest to attend; they often ignore surgery hours entirely and send absurdly urgent messages in unnecessary cases and then plead that they did not wish you to hurry. I myself have received a telegram from a club patient not asking for, but fixing, an appointment at the surgery for the middle of the afternoon, a time at which a country medical man is generally far from home. With ordinary patients these abuses can be checked to some extent by special fees for evening and night work, but not so with club patients.

With regard to the actual question of fees and the abolition of wage-limit Mr. Brabrook says, "all join for the same benefit." Now I maintain that they do not, and will try to explain myself. It may be taken that a member's subscription is paid to insure himself against two evils: (1) cessation of income during illness and (2) the medical man's bill. He cannot insure against sickness itself but can do so against its consequences. Whitaker's Almanack and other books of reference distinctly assert that medical fees are assessed upon a sliding scale, the reason of course being that the fees which the poor are able to pay are no adequate remuneration. The higher a man's income the better fees is he supposed to pay; therefore evil No. 2, the medical man's bill, will demand a higher premium according as the income is higher. If only the class for whom Mr. Brabrook speaks would take to heart his assertion that "there is much in the kindly service of a medical man that no money can purchase," there would be more chance of coming to terms, but too many still deny that a medical man is a free agent, preferring to look upon him as a public slave bound to go wherever and whenever sent for. Working men or, as they will soon have to be called, the leisured classes, should be the first to admit the value of short hours and should be ready to help the medical man to secure the same by seeing that he is better paid for the hours during which he does work. In any revision of club tariff, in addition to increased subscriptions, might there not also be inserted extra charges for late messages and night work, if only to draw the attention of members to the fact that such should be avoided as much as possible. This is only in accordance with the practice of the workman, who charges extra prices for overtime if he consents to do anything after the usual hours.

I consider that friction between clubs and their doctors would be lessened considerably if the latter were looked upon more as medical men and less as paid officials of the club. If a uniform rate for specified incomes and for a specified radius could only be arrived at then it ought to be possible for each member at the commencement of each year to choose to which doctor his subscription shall be paid. Each individual member would then have his own free choice and the power (which is sometimes used in an objectionable manner) of the committee would be practically at an end. Before Skill and Thrift, as Mr. Brabrook calls the two parties, can work together harmoniously Thrift must disabuse himself of the idea that Skill is making a fortune, but must, at the same time, admit that Skill has at least an equal right with the shopkeeper and the publican to make a decent living.

If friendly societies can only be brought to see these things in their proper light and will look upon medical men as their hard-working fellow-men I feel sure they will be willing to increase their own subscriptions instead of trying to persuade richer men to join them in sweating the club doctor. If they cannot see this in such a light they must remember that they have taught us that union is strength and that some day, perhaps, even the medical profession may rise in its might and assert its right to live by doing a fair day's work. I must apologise for the length of this letter, especially as I have not had nearly so much experience as many with clubs, but I wish to point out a few difficulties which have arisen within my own limited scope.

I am, Sirs, yours faithfully,
C. H. POWERS, L.R.C.P. Lond., M.R.C.S. Eng.
Gosforth, Cumberland, May 7th, 1901.

"ON THE CAUSATION AND TREATMENT OF PROFUSE EPISTAXIS IN PEOPLE BEYOND MIDDLE AGE."

To the Editors of THE LANCET.

SIRS,—May I send a few lines to supplement my paper on the above subject which appeared in THE LANCET of April 20th, 1901, p. 1133, and to answer some of your queries? In all my cases the hæmorrhage was purely passive —i.e., it was venous hæmorrhage due to an over-filled venous system. The patients were all with one exception over 60 years of age and were all what is commonly called "gouty," having suffered from eczema, &c., though only one had had an attack of true sthenic gout. The more or less chronic state of high arterial tension was, I think, due in all to what has been called "lithæmia," "uricacidæmia," &c.—a condition which so commonly produces cardio-vascular degenerative changes in well-to-do people of 50 years and upwards. In these cases there is usually no history of any injury or any great exertion or strain, but the patients as a rule complain of having felt tired and fatigued for some time, they get more easily out of breath, and feel going up-hill or upstairs to be much more of an effort than it used to be. These symptoms show that working against the long-continued high intra-arterial pressure has told on the muscular wall of the heart and has diminished its elasticity, or, in simple words, that these patients are suffering from tired hearts.

In many people whose circulatory system is in this condition some valvular disease is apt to be set up at about the age of 60 years from the excessive strain on the valves caused by this long-continued high pressure—i.e., the valvular and muscular structures of the heart are apt to fail at about the same time. In these cases the mitral valve tends to become diseased and defective rather than the aortic, which is curious, as in cases of heart strain from external work the aortic valve usually gives first, whilst the mitral certainly suffers most frequently where the heart strain is due to high arterial tension, probably because it has to resist the greatest strain set up during the systole. These patients with chronic high arterial tension and tired hearts must necessarily have at all times a tendency towards a faulty distribution of their blood in the various vessels, and their veins must as a rule contain too much blood. If to this state of circulation any additional hindrance to the flow of blood should supervene, such as a quickly developing valvular lesion, a sudden contraction of the peripheral vessels from exposure to cold, &c., the embarrassed heart must become still more unequal to its work and a condition of more or less intense venous congestion inevitably be set up. If so, nature will probably seek relief by some hæmorrhage and this tendency to hæmorrhage will continue until the venous congestion be relieved.

Unfortunately, the hæmorrhage tends further to weaken the already feeble heart and lands the patient in a vicious circle where hæmorrhage is followed by hæmorrhage. In these cases one attack of epistaxis if not properly treated is generally followed by another and the patient may be reduced to a condition of extreme weakness. In my cases of epistaxis I had no history of any sudden muscular effort or strain, but rather the complaint of having had tiring days or feeling very cold and chilly. In the three cases where valvular disease was found as a new feature I believe the epistaxis occurred when the heart was at its weakest, before it had become accustomed to the altered conditions caused by the valvular lesion and before any compensatory hypertrophy was established.

I am, Sirs, yours faithfully,
Brechin-place, S.W., May 7th, 1901. GEORGE COATES.

STERILISED MILK AND INFANT MORTALITY.

To the Editors of THE LANCET.

SIRS,—I am desirous of seeking information through the medium of THE LANCET with regard to certain details in the sterilisation or modification of milk for the purpose of reducing infantile mortality in manufacturing towns. By the

St. Helens scheme a basket is given to each customer containing nine bottles of sterilised, modified, or humanised milk, and with this a teat which can be fitted upon the end of the bottle. Directions are given to the mothers to feed the baby every two hours during the day and every four hours during the night, and to give the milk through the teat supplied. This seems easy and simple enough in theory. In practice, however, we have, in our endeavours to reduce infantile mortality, to cater for a class who through circumstances or indifference are unable to grasp the full object of the scheme. This class either refuse to use the milk at all or if they use it they pour the milk out of the sterilised bottle into an ordinary "titty bottle" with a long indiarubber tube or replace the teat with a long indiarubber tube of their own and thus save themselves both time and trouble. This materially alters the whole purport of the scheme, as the bottle or the tube used is generally in a state of sepsis, and the baby, instead of receiving pure wholesome milk, obtains it contaminated by admixture with the sour septic milk left from former feeds in the bottle or the tube, and this does not help to reduce infant mortality, but brings the sterilised milk scheme into disrepute.

Supposing the authority which supplies the milk were to obtain a quantity of these long flexible tubes and with every basket they supply, or in such cases as they consider it necessary or where the mothers prefer it, give one or two of these tubes (thoroughly cleansed), so that the child could be fed through this tube instead of the short teat, at the same time directions being given to the mothers that these tubes must be returned daily for cleansing, 1. Would this do away with the efficiency of the scheme? 2. Is it impossible to keep the long tubes clean? 3 Does the contact of sterilised milk with the length of indiarubber (thoroughly cleansed) contaminate the milk? 4. Is the objection to the long tube any other than that it is less likely to be thoroughly cleansed than a short one? 5. If the infant mortality of our manufacturing towns is due chiefly to the feeding of infants on improper food or feeding them out of dirty bottles and tubes, ought not authorities to try to render their scheme for educating and helping the mothers of such practical utility that even the most careless and indifferent could use the sterilised milk without feeling it to be an irksome burden? There is no doubt that the long flexible tube is used, and used to advantage, by many well-to-do people who keep it thoroughly clean, and I should like to know if the consensus of opinion amongst medical men is that milk must of necessity become contaminated the moment it passes through a length of indiarubber, and that the cleansing of this indiarubber tube is an impossibility.

I am, Sirs, yours faithfully,
E. A. CLARKE, M R.C.S. Eng., L.S.A.
Dukinfield, May 14th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. Walter Kidd is alarmed lest Dr. Reid's views should triumph on a foundation of Weissmannism. But it is one thing to assert that only inborn characters are transmitted, as Dr. Reid does, and another to *attempt* to explain how they are transmitted, as Weissmann has done. Nobody has spoken more emphatically than Dr. Reid on this subject. "Weissmann's speculations,"[1] he *says*, "*obscure* in themselves, made more obscure by his methods of demonstration, still more obscure by being constantly emended under the influence of destructive criticism, have *drawn* many students from the true path and by their difficulty have discouraged others." He speaks of Weissmann's views as "more or less metaphysical speculations concerning the continuity of the germ plasm and ids, idants, biophors, and so forth." Dr. Kidd's alarm would appear, therefore, to be groundless.

Dr. Clouston's remarks[2] concerning my criticisms are excellent in their brevity but deficient in argument of any kind; I will grant him his two irrelevant points cheerfully and humbly withal if he can destroy my criticisms or answer my challenge successfully.

I am, Sirs, yours faithfully,
H. LAING GORDON.
Honor Oak road, S E, May 12th, 1901.

[2] THE LANCET, April 27th, 1901.

SWALLOWING ARTIFICIAL DENTURES.

To the Editors of THE LANCET.

SIRS,—Deaths from swallowing artificial dentures are becoming alarmingly frequent and the operations for the removal of these irregular and spiky objects are very often also fatal. The cause of this fatality is, of course, the hooks and bands which project from the plate, bury themselves in the tissues, and can only be dislodged by still further lacerations. It has struck me that in the case of vulcanite plates (most plates are now made with vulcanised caoutchouc as a base) the removal of the denture could often be facilitated by its being divided *in situ* and the parts removed separately. This could be done by splitting it with cutting forceps or dividing the vulcanite by fusing it with the electric cautery at a not very high heat Metal plates could not be divided so easily, but it would be by no means impossible with strong shears.

I might also, in this connexion, mention that the swallowing of these dentures takes place as a rule during sleep. I do not wish to add another burden to the already over-laden general practitioner, but he would do well to warn any patient wearing a "partial" denture of the risk he runs, apart from hygienic considerations, by not removing his plate at night.—I am, Sirs, yours faithfully,
WM RUSHTON, L.D.S. R.C.S. Eng.
Harley-street, W., May 7th, 1901.

KING'S COLLEGE, LONDON, AND THE SOUTH AFRICAN WAR.

To the Editors of THE LANCET.

SIRS,—There is a large wish among old King's collegians and King's College school boys that the services of any of their number who have fallen in the war or who have survived the campaign in South Africa should have suitable commemoration. It will greatly facilitate matters, in view of an early meeting of sympathisers with the movement, if the names of any who are worthily entitled to inclusion in the roll of honour be immediately communicated. The medical representation must necessarily be a very large one and through the medium of THE LANCET we shall doubtless receive the names of a goodly number of King's College men, dead and alive.

I am, Sirs, yours faithfully,
J. TREEVE EDGCOME,
Associate of King's College, London.
Inner Temple, E C, May 6th, 1901.

SOUTH AFRICAN CIVIL SURGEONS' DINNER.

To the Editors of THE LANCET.

SIRS,—We have received so much support in reply to our letter published in THE LANCET of April 27th, p. 1236, that we feel justified in asking you to announce that the dinner will be held on Wednesday, June 5th, at the Hotel Cecil at 7.30 P.M. The price of the tickets will be 10*s*. 6*d*. each. We shall be glad to hear as soon as possible from any civil surgeons who may desire to be present. We shall be further obliged to you if you will kindly publish the following list of those who intend to be present: H. A. Ballance, A. A. Bowlby, J. Paul Bush, E. G. Calverley, J. Lenthal Cheatle, W. Watson Cheyne, John Chiene, A. Conan Doyle, H. W. Dudgeon, W. V. Eaves, A. D. Fripp, J. F. R Gairdner, A. Granville, E. A. Houseman, Sir W. MacCormac (chairman), G. H. Makins, H. T. Mursell, T. H. Openshaw, F. O. Stoehr, C. Stonham, H. J. Starling, Sir W. Thomson, H. H. Tooth, F. E. Walker, and P. Wood.

We are, Sirs, yours faithfully,
C. GORDON WATSON, } Acting Secretaries.
FRANCIS E FREMANTLE, }
30, Moore-street, Lennox gardens, S W.

AN APPEAL TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—I appeal to medical Freemasons to assist me in getting Reginald Everard Adolphe Webster, aged 10 years and three months, into the Royal Masonic Institution for Boys at the October election, which will be his first and only chance. Bro. Dr. Webster, the father, was P.M., Lechmere Lodge No. 1874, and was until recently a member of the Addiscombe Lodge No. 1556. He died this year from acute pneumonia after a brief illness, leaving a widow and four children practically unprovided for. I would be glad to receive votes for any of the Masonic institutions.

I am, Sirs, yours faithfully,
HENRY G. THOMPSON, M.D. R.U.I.

110, Cannon street, E C, May, 1901.

THE MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET.

SIRS,—In common with the other governors of the Medical Benevolent College, Epsom, I have just received my annual voting-paper together with a recommended list of candidates drawn up by a committee of the Council, and it is to this document that I wish to call attention. There are 19 candidates for four vacancies for pensions, five being males and 14 females, but the recommendation committee, as in many former years, entirely ignores the men. Why, may I ask, is the broken-down practitioner to be always passed by in favour of a widow? This year's list is headed by the name of a practitioner, aged 69 years, which appears for the *ninth* year and has never yet had the recommendation of the committee though the applicant has scraped together 2021 votes, and has now died before the election! Then we have a practitioner of 79 applying for the *fifth* time and another of 79 for the *fourth* time. Surely the necessities of these gentlemen must equal those of widows of 62 and 64 who are recommended by the committee. I have no knowledge of the committee or their methods of investigation, but it seems odd to the outsider that they should recommend four candidates who have already secured 3558, 2756, 2770, and 3029 votes respectively, and who are therefore almost certain to secure their election without much assistance.

When I turn to the candidates for Foundation Scholarships I find the same tendency to recommend those candidates who have already secured large numbers of votes and therefore must have influential friends. I quite approve of supporting "last applications," but I think some of the seven cases selected are on the face of them open to criticism as compared with others who have not been so fortunate in securing votes. I need hardly say that I shall not support the list recommended.

I am, Sirs, yours faithfully,
AN OLD GOVERNOR.

GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p. 1305.*)

Extirpation of the Gasserian Ganglion.

PROFESSOR KRAUSE (Berlin) gave an account of 25 operations performed by him for neuralgia of the trigeminal nerve and described the details of his method. In typical neuralgia the operation was successful in every instance; in other conditions, such as in hysteria, rheumatism, &c., it was useless. The operation was sometimes followed by slight sensory disturbances, such as sensations of pricking, &c.; paresis of the muscles of the eye and keratitis have also been observed. Some of the patients have remained well for between five and six years.

Castration for Tuberculosis of the Testicles.

Professor VON BRUNS (Tübingen) said that castration was not now performed so frequently as it used to be and double castration was avoided as much as possible because psychical troubles were said to follow this operation. There were also cases in which castration, in the full sense of the word, was not necessary, because sometimes, and especially when the disease was progressing but slowly, the removal of the tuberculous portions of the testicle or the epididymis was sufficient. Professor von Bruns had collected the statistics of the cases of this disease which had been met with at the Tübingen surgical clinic during the past 50 years. He was able to examine 112 cases, comprising 79 in which the disease was unilateral and 32 in which it was bilateral. The disease began nearly always at the epididymis; in 24 per cent. the testicle was affected with tuberculosis six months afterwards, and in 40 per cent. one year afterwards. In 26 per cent. the second testicle became tuberculous after the first had been removed. As to the results of unilateral castration he had found that 13 per cent. of the patients died, that in 15 per cent. of the cases tuberculosis of other organs occurred afterwards, that in 26 per cent. the other testicle became tuberculous, and that in 46 per cent. there was permanent cure. After bilateral castration as many as 56 per cent. of the patients were permanently cured. With regard to tuberculosis of the uropoietic system he stated that it was not more frequent in connexion with tuberculosis of the testicles than in connexion with tuberculosis of the other internal organs. His final conclusion was that the results of castration were not so bad as had been suggested.

Professor BAUMGARTEN (Tubingen) gave an account of his experiments on tuberculosis of the urogenital organs. He had tried to ascertain by experiments on animals whether it might be possible to produce tuberculosis of the bladder and kidney by injections of cultures of tubercle bacilli into the testicle. It had been proved that the tubercle bacilli never moved in a contrary direction to the circulation of the lymph but always with it. They had no power of motion of their own, but were carried along by the lymph-stream. Tuberculous disease might therefore reach the bladder from the testicles, but not *vice versâ*.

Professor BUNGNER (Hanau) recommended "castratio alta." He removed not only the testicle, but also most of the vas deferens. The incision must thus be made rather large and the remainder of the vas deferens was removed by evulsion. It had never happened that after this operation tuberculosis extended to the peritoneum, as suggested by Dr. Schede.

Dr. SIMON (Heidelberg) reported 92 castrations for tuberculosis of the testicle, 66 per cent. of which resulted in cure. In 24 per cent. pulmonary tuberculosis was present, and it was found that the disease of the lungs was favourably influenced by the castration. Of 29 cases of bilateral castration eight patients died afterwards from tuberculosis and 21 were still alive. Psychical troubles occurred once.

Effects of Modern Artillery and Rifle Fire.

Surgeon-General W. SCHJERNING (Berlin) said that hitherto wounds from artillery fire were relatively rare, but henceforth they would be more frequent owing to the use of quick-firing guns and the greater precision of modern artillery. Wounds inflicted by shrapnel would be specially liable to infection by foreign bodies, such as portions of uniform being driven into the wound, so that 96 per cent. of those who were struck would be disabled. The same was the case in wounds from splinters of shells. In future wars probably more men would be killed at once on the battlefield by small calibre bullets, especially when the opponents came to closer quarters than had been the case in the South African war. Those who survived and were carried off the battlefield would, however, have a greater chance of recovery than had been the case in former wars, owing to the progress of operative surgery and the improved arrangements of the army medical service. This was especially evident in wounds of the abdominal organs, where laparotomy, when performed from 12 to 24 hours afterwards, would save a good many of the wounded.

Dr. TILLMANN (Greifswald), who had studied the specimens in the Army Medical Museum at Washington, U.S.A., stated that in former wars the wounds were not so severe as they were now. Nevertheless, the number of amputations was enormous because the great majority of wounds became infected.

Other papers read before the Congress dealt with the following subjects: Operations for Cleft Palate, by Professor VON EISELBERG (Vienna); the Parasites of Cancer, by Dr. NILS SJOBRING (Lund); Cerebral Surgery, by Professor HEIDENHAIN (Worms); Appendicitis, by Dr. REHN (Frankfort); and Contractures of the Knee-joint, by Dr. HEUSNER (Barmen). Professor KOCHER was elected President for the next meeting of the Congress.

NEW HOSPITAL AT NEWPORT (MON.).—The new hospital which has been erected at Newport (Mon.) will be formally opened by Lord Tredegar on August 5th. The institution, which will contain 84 beds and stands on an area of four and a half acres of land, has been built at a cost of about £30,000.

THE ORGANISATION OF THE PROFESSION IN FRANCE.

(FROM OUR SPECIAL COMMISSIONER.)

AFTER-EFFECTS OF THE INTERNATIONAL CONGRESS OF DEONTOLOGY.

THE International Congress of Medical Deontology, which was held in Paris in the month of July last year, has been bearing fruit. The desire for organisation has spread in the ranks of the medical profession in France just as it is spreading in England. On several occasions the medical organisations that exist among our near neighbours have been described in these columns, notably the Association Générale des Médecins de France, the Concours Médical, the Syndicat des Médecins de la Seine, l'Union des Syndicats Médicaux de France, &c. But these organisations, though accomplishing useful work in their respective spheres of action, should at least occasionally be grouped together for a common purpose. The remarkable paper on Medical Deontology read at the International Congress by Dr. Grasset of Montpellier led to the adoption by the entire Congress, at its final sitting, of the following resolution:—

> The First International Congress of Professional Medicine and Deontology, considering that, apart from the International Commission which has been constituted, it is also necessary to form in France a permanent national committee for the purpose of (1) preparing the national participation in the next International Congress, (2) of drawing up a project of a deontological code which shall be submitted for examination and discussion to all our colleagues, (3) of [illegible]

The above resolution constitutes the first attempt to federate all the medical organisations of France, and the representatives of these various societies met last Easter at the Paris Faculty of Medicine. It soon became evident, however, that in spite of the resolution considerable difference of opinion prevailed. Several of the medical men present manifested a strong preference for the constitution of medical chambers after the model of those that exist in Germany and Austria The reports as to medical chambers that had been given at the International Congress had not, however, been very favourable. The fact that every medical practitioner would be compelled by law to subscribe to, and to obey the rules and discipline of, medical chambers had its advantages; but, on the other hand, the dependence upon the government involved would mar freedom of action and would prevent the profession from attending to many questions that might be of considerable importance. Nevertheless, it was maintained that many advantages had resulted from the constitution of medical chambers in Germany and Austria which had not been mentioned at the International Congress. After some considerable discussion the matter, however, was allowed to drop and the attempt to revise the decision adopted at the Congress collapsed. On the other hand, it was felt that the Committee actually constituted by the resolution quoted above was lacking in authority and it was determined that some effort should be made to obtain some recognition and sanction from the Government. For this purpose the President of the Committee, Dr. L. Lereboullet, proceeded to the Ministry of the Interior, where M. Henri Monod holds a post similar to that of the chief of the medical department at the British Local Government Board. M. Monod, however, when asked what would be the attitude of the French Government, held out no encouragement. He seemed to fear that a clash might occur between the organised members of the medical profession and the medical men in the employ of the Public Assistance Service whose position bears some analogy to that of the medical men who in England hold official posts under the Poor-law. M. Monod did not relish the idea of the creation of a Superior Council of the medical profession with the aid of, and under the patronage of, the Government. He thought that such an organisation should be independent of all Government authority and control.

Dr. Lereboullet then proceeded to the Ministry of Public Instruction, which, as the controlling authority over the universities and faculties of medicine, is also concerned in the interests of the medical profession. Here M. Liard, the Director of the Secondary Education Department, expressed much sympathy. He readily recognised, and he emphasised the fact, that the medical profession was in serious difficulties. Indeed, he went so far as to say that in his opinion a terrible calamity was at hand. An unprecedented number of medical students had entered at the Faculties of Montpellier, Toulouse, and Bordeaux. Any number of small farmers, petty tradesmen, and others who were able to scrape a little money together were now sending their sons to the universities so as to make medical men of them. There would be a terrible glut in the urban supply. There were not too many medical men in France, but all the young men gravitated to the large centres and especially to the northern towns. For small rural practices there was still need of medical men, but the newly-qualified practitioner was generally too ambitious to accept such a modest position. Thus the glut was due to bad distribution rather than to an over-supply of medical men. M. Liard was of opinion that it would be a good thing if a law were enacted constituting some sort of institution that could act as a governing body for the entire medical profession. There is no General Medical Council in France similar to that which exists in England and there is neither Register nor authority willing or able to remove from the profession an unworthy practitioner. The Superior Council of Hygiene is supposed to possess this power, but it has never exercised such a function. No proposal has even been made to this body to deal with professional questions; it has never attempted to do more than to advise the Government in matters relating to the preservation of public health.

Finally, Dr. Lereboullet went to the Ministry of Commerce and Industry. Here he was most cordially received. M. Millerand said that he would favour the creation of a medical council that would have for its mission the studying of all questions of social protection. First would come the protection of the economical interests of the medical men themselves, and after that their connexion with other corporations, collectivities, trade organisations, &c. This somewhat alarmed some of the medical men. To their fancy these suggestions seemed not unconnected with the principles of State socialism, they feared the introduction of politics in their midst and, when gathered together to hear the results of these various negotiations, a large majority voted that no further effort should be made in this direction. It is also necessary to recognise that the desire to create a central and supreme authority is not viewed with absolute favour. Theoretically, all must acknowledge that one great powerful organisation is preferable to many weak bodies, but in practice each collectivity has an individuality of its own and does not always relish a process of absorption, and some of those who have considered themselves as chiefs do not always care to become subordinates. At present the tie of union is so slender that each particular society is able to continue its own individual life without check, control, or interference, and it will need some sharp necessity to make these different groups or organisations abandon their independence. Yet among the members of the profession at large, and especially among those who do not belong to any special organisation, the need of a central and supreme body is widely felt. This is proved by the fact that though such a body can hardly be said to exist hundreds of medical men have acted as if it was actually not only in being but possessed of very extensive powers. No sooner was it generally known that, by virtue of the Grasset resolution, the Organising Committee of the Deontological Congress had become the Permanent National Committee of Professional Medicine than innumerable letters came pouring upon the general secretary, Dr. Jules Glover. Though possessing no power to act, no secretaries, and no funds to help him to carry on so vast a correspondence, Dr. Jules Glover has received as many as 30 letters in one single day, coming from all parts of France or the colonies and some even from abroad, and raising complex questions or making extraordinary requests. Sometimes it is a medical man who is losing his practice through the competition of a quack, another has a quarrel with a fellow practitioner, not a few want to change their practices, to remove to some more suitable or agreeable locality, or to prevent some newcomer from establishing himself in their immediate neighbourhoods. Then there are endless disputes with friendly societies, insurance companies, colliery or factory owners, &c. Dr. Glover does not know what to do with this vast correspondence, and sometimes he calls on the Dean of the Faculty, Dr. Brouardel, and lays before him a formidable bundle of letters. Dr. Brouardel suggests that Dr. Glover should as yet do nothing, for no one has the means or the power to take action at this stage. But all this proves that there is a real need of some better organisation and of some sort of council, committee, or professional tribunal to which many of the questions raised by the correspondents could be referred with the hope of obtaining a solution. In his replies to these letters Dr. Glover refers his correspondents to such societies as exist and that deal with the questions raised, but in many cases there are no societies to which such reference can be made.

As matters now stand there is some question of creating an Order of Doctors. Presumably it will be an honour to belong to this order, and those on whom this distinction is conferred will be expected to observe those ethical or deontological rules which after all should be carried into practice by every member of the profession. It cannot be said that certain medical men are bound by a code of honour which other practitioners need not observe. Every good rule should apply equally to all. This question of an "Order" seems to be but playing with words. Organisation and discipline to carry out a definite set of principles are greatly needed and it does not much matter under what name this end is attained. There is now the beginning, though but a small beginning, of the necessary and centralised organisation. The Permanent National Committee of Professional Medicine has arranged to meet at least twice a year at the Paris Faculty of Medicine. Here will be centralised the questions that have arisen in the various medical organisations that are represented on this National Committee It remains for the medical practitioners, for the rank and file of the profession, to enrol themselves in their local medical syndicates or unions and thus to render the National Committee a truly representative institution. At present it has only a moral influence. It has not even constituted a committee or tribunal of discipline, but it has appointed a sub-committee to draw up the draft of a code of deontology. As is usual, there is more said about the grievances and the rights of medical men than about their duties, but this will come in due time. The work of organisation is slow but it is better that a small body of men who are all absolutely unanimous should work the object in view than a crowd lacking in cohesion. When the profession, by the steadily pursued work of organisation and the federation of organisations, has found the means of articulating and rendering its desires manifest what legal sanction may be needed will then be attainable. In any case the First International Congress of Medical Deontology has not been held in vain, for it has brought into existence the Permanent National Committee of Professional Medicine, and that the Congress itself was a success is still further proved by the report which this committee has just issued. According to this statement, 55 000 circulars were sent out for the International Congress. These were printed and posted by the French Government free of cost. The subscriptions or entrance fees of the members of the Congress amounted to 9995 francs. The Paris Municipal Council gave the Congress a subvention of 3000 francs, and with some small donations and the sale of reports of the proceedings to persons who were not members of the Congress the total receipts amounted to 13,349 francs, or £534. The expenses, including £72 for the banquet, amounted to £442, so that there remains a balance of £92 in hand to help in the organising of the next International Congress which will be held at Brussels in 1903

For this next International Congress each nationality should have an organising committee of five members with a representative who resides in Paris, and these committees of patronage have already been appointed in the United States, in Belgium, in Holland, and in Spain. These national committees will endeavour to promote the interests of the Congress and will urge societies to send representatives; they will have a voice in the preparation of the programme. The permanent committee of the first International Congress has its headquarters in Paris, with Dr. Jules Glover, 23, rue de la Bienfaisance, for its general secretary. This body is taking the initiative for the appointment by each nationality of a local national committee of patronage. Someone must do this work and the only committee in existence and able to meet is the committee which organised the first Congress when it was held in Paris It therefore at present serves as the international connecting link and will continue to do so until the Congress meets again in Belgium. This work will then probably be taken up by the Belgian committee upon whom will fall the organisation of the Second International Congress to be held in Brussels in 1903.

Paris, May 4th

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—The Pasteur Institute at Kasauli—Laboratories for Experimental Research.

THE intensity of the outburst of plague in Bengal is at last abating, although the disease continues in other parts of India without much change. For the whole of India there were 8429 deaths from plague last week, as compared with 11,616 in the previous week. In Bengal the figures dropped from 7881 to 4735. The North-West Provinces report 929 deaths as against 909, the Punjab 393 as against 301, Karachi 219 as against 176, and Bombay City 714 as against 707. Twenty-five deaths are reported from Kashmir. In Calcutta the outbreak is rapidly going down—the plague mortality having fallen from 859 to 548. The returns show that there have been 6212 deaths from plague in this city since the beginning of the year. There is a slight rise in the plague figures for Bombay, but these figures are utterly untrustworthy Notwithstanding the proved value of inoculation for plague the prophylactic is being pushed in a half-hearted sort of way and in many places it receives little encouragement from the higher authorities The issue of doses from the Research Laboratory, Bombay, the week before last was 10,020 to Bangah in the Jullunder district of the Punjab, 4000 to Jullunder, 2000 to Gurdaspur, Agra, and Karachi, 1182 to Gaya, 1206 to Kashmir, and 1000 to Falma in Marwar. Very few inoculations are being done in Bombay city and practically none at all in Calcutta

The work done in the Pasteur Institute at Kasauli from its opening in August last up to March 8th included the treatment of 173 patients. The lists are made up as follows: British officers, 15; British soldiers, 45; native officers, 1; soldiers, 9; European civilians, 27; soldiers' children, 3; natives, 73. The success so far in the treatment of these cases equals that of the Pasteur Institute in Paris and the institute will prove a pecuniary gain to the Government in the long run. What are now wanted are well-equipped research laboratories in Calcutta and Bombay, where original researches should be made by the officers in charge and could also be made by private investigators. The field for original work in bacteriology and experimental pathology in India is enormous, but with the exception of one or two small efforts at cultivation it is all running to waste. What scientific work do we hear of in the treatment of plague, of cholera, of relapsing fever, and of the anomalous fevers which men are so fond of writing about? Can it be said that we have advanced a single step in the treatment of these diseases during the past four years? And why? Because there is no organised experimental research. Take Bengal, the reputed home of cholera. Is there a single man deputed to work upon and to investigate this disease? Cholera inoculation has got to a certain stage, but it gets no further, and there is absolutely no scientific treatment after the symptoms of the disease have once commenced. What have the scattered workers done in plague? The treatment is still stimulants strychnine, and digitalis, and the mortality is still nearly 80 per cent Nothing can be done without experimental research and laboratories cannot be supported except by Government or by public bodies. The men must be found to be put upon the work, it is utterly impossible for it to be taken up as a hobby.

April 20th.

The Decline of the Plague Epidemic.—The Famine.—The American "Diploma Mill" and Indian Victims.—Return of Hospital Ships from China.

A further large reduction in plague mortality occurred last week. The total deaths throughout India were 6304 as compared with 8429 for the previous week. The decline was general with the exception of the Punjab where the deaths rose from 393 to 518 The most marked fall was noticeable in Bengal where the deaths fell from 4735 to 3258. The outbreak in Calcutta is rapidly subsiding, the deaths from plague having declined from 548 to 389, and the general mortality of the city having returned nearly to normal. The Saran, Gaya, and Patna districts, recently suffering so severely, return much reduced figures, but in the outlying villages of the Saran and Patna districts the disease is still very virulent. In the North-West Provinces there has been a decline from 929 to 662 and in Bombay city from 714 to 602. In Calcutta the general mortality keeps very high, the last published weekly total giving 1667 deaths—equivalent to an annual death-rate of 109 62 per 1000. The city of Karachi is still severely afflicted with the pestilence, but an improvement can be calculated upon very shortly. The Jumna district of Kashmir returned last week 25 deaths.

It is, perhaps, hardly realised in England that the famine still continues. The returns for last week show over 250,000 persons on relief in British territory, nearly all of whom are in the Bombay Presidency. Portions of the Hyderabad State and the Baroda State are also still famine-stricken.

The Government have published certain extracts from American papers recording the conviction of the two Armstrongs who conducted a "diploma mill" and sent many of their "diplomas" to India. Several native practitioners were deluded by these rogues, who are said to have been turning out graduates at the rate of 1000 a year. First they styled themselves the Illinois Health University. When this was stopped the Independent Medical College was started, and when this was annulled the Metropolitan Medical College came into existence. It is highly satisfactory to hear that imprisonment for one year has been imposed on James Armstrong, the so-called President, and that though the sentences have been deferred on his coadjutors they are also likely to be punished. This is a good example of the necessity for some form of registration in India. At present any quack is free to assume any titles he chooses and to delude the public as to the possession of medical knowledge. The recognised graduates of colleges in India should be separately registered, and it might be possible also officially to acknowledge the native hakims and vaids who practise with native drugs and methods of treatment.

The hospital ship *Carthage* has arrived from China, bringing troops collected from Peking, Tientsin, Taku, and Shanghai Kwan. She brought 225 native rank and file and 157 followers There were also 20 British non-commissioned officers and men and a few commissioned officers. The hospital ship *Gwalior* is expected shortly with sick and invalids. Arrangements are now being made in Calcutta to fit up transports to bring back the Imperial service troops—viz , the Jodhpore Lancers and the Bikaneer and Ulwar regiments.

April 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

A New Anti-malaria Experiment: a Munificent Offer.

THE theory of the connexion between mosquitoes and malarial fever will shortly be put to a very practical test If the theory strongly held by Major Ronald Ross, late I.M.S , the director of the Liverpool School of Tropical Medicine, and others that the anopheles is the bearer of the germs of malarial fever be a correct one, it follows that the extirpation, in certain districts at least, of the noxious insect must tend to minimise the danger of malarial infection. Doubtless to many it would appear to be utopian to attempt a task so apparently hopeless; nevertheless, given the means the experiment is worthy of trial. With this laudable object in view, and with great munificence, a Glasgow citizen who desires to remain anonymous has placed at Major Ross's disposal a sum of money sufficient to defray the expense of one year's trial of the measure in some malarious town or district in West Africa. To carry out this object a staff of workers with all necessary appliances will shortly be despatched to Sierra Leone to assist in the extirpation of the mosquito. The plan of operation will be to destroy the adult insects which are found in the houses and the larvæ which are deposited in puddles or vessels of water outside. The selection of the town where the experiment will be tried will largely depend upon the degree of coöperation afforded by local authorities Should the experiments prove efficacious an incentive will have been given to local authorities to induce them to adopt similar measures in other malarious towns. The Liverpool School of Tropical Medicine is also to be congratulated upon Major Ross's recent nomination as a Fellow of the Royal Society.

The Population of the City: A Disputed Death-rate.

Dr. E. W. Hope, the medical officer of health, has persistently held that the percentage of deaths to the population was based on an erroneous estimate of the population of the city. It would now appear that he had good reason for disputing the Registrar General's returns which, as he pointed out at the last meeting of the Health Committee, were 50,000 below the actual figures as shown by the recent census returns The average death-rate in the city during the past five years was now shown to be only 23 1 per 1000 instead of 25 per 1000, as computed on the erroneous estimate of population The population of Liverpool has now increased to 685,000, a considerable advance on the census of 1891.

The Progress of Cremation in Liverpool

Cremation makes slow progress in Liverpool. During the year 1900 40 bodies were cremated, bringing the total number cremated since the opening of the crematorium in 1895 to 102.

A New Departure at the Toxteth Workhouse.

Miss Agnes F. Blackadder, M.A , M.D. Glasg., has been appointed to the post of assistant medical officer to the Toxteth Workhouse. The board were somewhat divided over the appointment, but as there were four lady members present (naturally in sympathy with their sex) the young Scotch lady carried the day. It does not appear that any male candidate applied for the post.

University College, Liverpool: Meeting of the Court of Governors.

Dr. T. R. Bradshaw, the recently elected honorary physician to the Royal Infirmary, has been appointed a lecturer on clinical medicine in University College The court of governors of the college at their meeting on May 11th unanimously agreed that the time had come when Liverpool should possess a university of its own and gave some cogent reasons for the conversion of University College into the full-blown University of Liverpool.

May 14th.

WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENT.)

The Census Returns and Revised Death-rates.

NOW that the census returns of the county boroughs have been published it is possible to calculate the extent to which the birth-rates and death rates in these towns require re-adjustment. The population of Bristol is barely 1000 above the estimate of the Registrar General, so that the vital statistics based upon that estimate are not appreciably affected. The medical officer of health of Bath estimated the population of that city in the middle of 1900 at 52 600 and the death-rate for the year at 16 per 1000, but the actual population at the end of June, 1900 is found to have been 49,600 and the true death-rate 16 9 per 1000 The Newport population was over-estimated by the medical officer of health to the extent of about 10 000. The revised returns give the population of this seaport on April 1st last as 67,279; in 1891 the population was 54,707. The actual population of Swansea at Midsummer, 1900, was more than 11,000 below the 105,472 upon which the returns for 1900 were calculated, and the birth-rate is consequently raised from 26 7 to 29·7 per 1000 and the death-rate increased from 17·1 to 19·3 per 1000. At Cardiff, however, there is the greatest disparity between the estimate of the Registrar-General and the actual population as shown by the census returns. At the middle of 1900 the official estimate of the population was 194 247, or 35,000 more than the real number as disclosed by the census. The true birth-rate in 1900 was therefore 32·2 per 1000 and not 26 8, and the true death-rate was 16·5 and not 13 8 per 1000 as calculated from the higher estimate. In the last decade the population of Cardiff increased by 33,000 and there were 10,000 houses and shops erected during the same period. In each of the two previous decades the increase was about 45,000. Those interested in the matter quite expected to find that the Registrar-General had over-estimated the population, for the low birth-rates recorded during the past few years were exceptional, and it was known that there was a very large number of unoccupied houses in the town, but it was hardly anticipated that the discrepancy would have been as great as that revealed by the census returns. In his report for the year 1899 Dr. Edward Walford stated that with a view of ascertaining as far as possible the extent of the error in the official estimate of the population an inspection of the district is made in the month of June in each year in order to record the number of inhabited houses in the borough, and an estimate of the population is then made by multiplying this number by the average number of inmates in each house as found at the previous census. In 1899 this local estimate was only 5000 below the estimate of the Registrar-General and affected the death-rate to the extent of only 0 5 per 1000. It would thus appear that the average number of persons per house, which in 1891 was 6 3, must at the present time be very much less.

Knackers' Yards.

An account has already appeared in THE LANCET[1] of the committal to prison of a butcher trading at Taff's Well, Caerphilly, for selling horseflesh as human food without indicating that it was horseflesh. The meat was bought at twopence a pound from a well-known knacker who carries on a large trade in the colliery districts surrounding Pontypridd. This man was convicted at the Pontypridd police-court on May 3rd and fined the maximum penalty of £20 for not complying with section 1 of the Sale of Horseflesh Regulation Act, 1889, which requires those who sell horseflesh for human food to place in a conspicuous place upon their premises and so as to be visible day and night a suitable sign indicating that horseflesh is sold there. Until Nov. 1st 1894, knackers' yards were licensed and regulated by the court of quarter sessions and after that date, outside London, by the local sanitary authorities. The Towns Improvement Clauses Act, 1847, is the statute principally concerned with these premises, but there are several older Acts still unrepealed which contain provisions relating to horse-slaughtering. The first purpose of these Acts was no doubt to prevent horse- and cattle-stealing, but there is no reason why they should not be used on occasion to prevent the distribution for human consumption of unsound meat. The vestry still has the power, and indeed is under an obligation, to appoint annually an inspector of houses and places for slaughtering horses. A person convicted under the provisions of one of these Acts may be punished, not only by the cancellation of his licence, by fine, or by imprisonment, but by whipping.

Cardiff Infirmary.

As already stated in THE LANCET[2] Lady Windsor, Lady Aberdare, Mrs. Mackintosh of Mackintosh, and Miss Talbot recently appealed to the ladies of Glamorganshire for sufficient funds to enable the number of beds in the Cardiff Infirmary at the disposal of Dr. John D. Williams, the gynæcological surgeon, to be increased. The response to the appeal has been very gratifying and is such as to justify the opening of a ward with 10 beds which it is proposed entirely to refurnish.

Colliery Surgeons.

Dr. C. E. Cochrane was on May 10th elected by a majority of 900 votes surgeon to Messrs. Insole's colliery at Cymmer in the Rhondda Valley. Dr. Cochrane is a son in-law of the late Mr. Ivor A. Lewis who had been surgeon to the colliery almost from the sinking of the first pit. With one exception all the colliery surgeons in the Rhondda and Pontypridd districts are paid a poundage of threepence upon the earnings of the colliers. The system which has been adopted in some of the Monmouthshire coalfields, notably in the Rhymney Valley, of paying a fixed salary, has never found much favour in the Rhondda Valley where the workmen appear to be alive to the fact that although in good times the surgeon is well paid, yet in bad times he is very inadequately remu rated and during a strike receives actually no payment at but must still remain in attendance upon those requiring h services. The one exception mentioned above is in the cas of the Ferndale collieries, to which for many years Mr. T. W. Parry has been surgeon. The work-people employed at this and at the adjoining collieries paid a poundage of only twopence until the year 1899, when it was raised to threepence at all the collieries except those at Ferndale. Mr. Parry thereupon gave notice that he would decline to attend any families from which the higher sum was not paid. A large proportion of the workmen paid the threepence, but a section of them formed themselves into a committee, made a levy, and engaged a surgeon at a fixed salary, the committee undertaking to pay the surgery expenses, &c. Several abortive attempts have been made to compel all the workmen to subscribe to the funds of this committee, but at present a majority of the colliers allow the deduction of threepence to be made for Mr. Parry. It is not without interest to remark that the leaders and the more intelligent among the men realise that when they themselves claim to be paid the "standard" rate of wages the same principle must be allowed to all paid workers, whether bishops or bootblacks, and that colliery surgeons have a perfect right to demand to be paid at their "standard" rate.

High Death-rate in Breconshire.

The death-rate recorded in the rural district of Hay in Breconshire, where there is a population of 3200 persons, was 19·2 per 1000 and the infantile mortality was equal to 205 per 1000 births. There were only 16 more births than deaths during the year in this district.

Medical Certificates.

At the April sitting of the Aberdare County Court Judge Gwilym Williams animadverted upon the careless manner in which certificates of inability to work were given by medical men to their patients, and said that in future he should be very chary of accepting such certificates except from those medical men who were personally known to him. These remarks were called forth on the presentation of a medical certificate to the effect that a collier against whom an execution summons had been applied for was too ill to work. It was stated that for nearly a year similar certificates had been lodged in court and execution had in consequence been deferred, whereas the man had been at work nearly the whole of the time. It appears that this carelessness is not to Aberdare, for at the Newport County Court May 10th Judge Owen said that as he was getting untrue medical certificates he would have to ref recognise them.

Bristol Medical Dramatic Club.

The Bristol Medical Dramatic Club gave a series of formances last week at the All Saints' Hall, Clifton, in a the funds of the Bristol Royal Infirmary and the Bri General Hospital. The pieces selected were *The Man in* *Street* and *The Parvenu*. The performances were very su cessful, and it is hoped that a substantial sum will be raise for the institutions.

May 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University.

AT the half-yearly meeting of the General Council held on May 1st the Finance Committee reported that the matriculations of medical students which were 2003 in the session 1889–90 had been declining ever since, and in the session 1899–1900 were only 1368. It was suggested that this result might be due in part to the competition of other schools and in part to the increasing amount of study required. The subject has naturally aroused much interest in Edinburgh and is being discussed in the newspapers. Dr. Ernest E. Greville, writing in the *Edinburgh Evening News* of May 11th, complains that owing to the operation of the "fee fund" an undue proportion of the fees paid by medical students is devoted to purposes other than medical instruction—namely, in making up the salaries of 22 professors who in other faculties have not sufficient students to cover expenses. He also complains of the professors' duties being in part performed by assistants and of the number of lectures that students have to attend encroaching on their practical work.

---

[1] THE LANCET, April 27th, 1901, p. 1219

[2] THE LANCET, March 30th, 1901, p. 929.

Glasgow University.

The University Court at its meeting on May 9th was again occupied with the question of finance. Dr. McVail's criticism at a former meeting of the arrangements under which the class fees of women students at Queen Margaret College are paid into the general fee fund was met by a reference of the whole question to a special sub-committee The report of this sub committee supported the existing arrangements, and its adoption was moved by Professor Stewart. Dr. McVail, however, remained unconvinced. He argued that the fees paid by the women students should be directly employed in remunerating their teachers. Paid into the fee fund, which was in the first place absorbed in meeting the normal salaries of the professors, it might well happen that the money would find its way into the pockets of those who were in no way concerned with the teaching of women, whilst the remuneration of the lecturers to women came as a charge on the general university fund. The arrangement, he said, was wrong in principle and bad in practice, and was one never contemplated by the ordinances. On a vote being taken Dr. McVail found only one supporter, whilst seven members voted for the adoption of the report.—The committee appointed to consider the proposal for the establishment of a summer session in Arts recommended the Court to approve generally the scheme advised by the Arts Faculty and to send on the proposals to the other Scottish universities for their opinion. This report was unanimously agreed to —The arrangements in connexion with the celebration of the ninth jubilee in June are exciting, as was to be expected, much enthusiasm among the undergraduates, who are heartily coöperating with the plans of the Court and Senate and who intend, in addition, to have some festivities of their own. Student representatives have been invited from the principal universities all the world over, and it is proposed to entertain the foreign visitors at a grand gaudeamus to be held in the Union on June 12th. The musical arrangements for this are in the hands of a committee presided over by Professor J. Glaister. On the evening of the 14th a university ball is to be held, and during the four days over which the celebrations are to extend the university athletic club is to hold the annual athletic sports and an athletic inter-university contest is to take place.—The following appointments to examinerships have been made by the University Court: William Hunter, M.D Edin., F.R C P. Lond., to examine in medicine and clinical medicine; Albert Carless, B.S. Lond , F.R C.S Eng , to examine in surgery and clinical surgery. Each appointment is for four years, dating from Jan 1st, 1901.

The Epidemic of Small-pox in Glasgow.

The last fortnightly report shows a register of 28 new cases of small-pox as compared with 92 new cases during the preceding fortnight; the deaths during these two periods were six and 16 respectively. The totals since the beginning of the outbreak are: admissions 1817, deaths 230. The number of those in hospital is 75 At a meeting of the Finance Committee of the corporation on May 10th the treasurer asked for instructions regarding the manner in which the extraordinary expenditure arising out of the outbreaks of bubonic plague and small-pox should be dealt with. After consideration the committee agreed to recommend that such expenditure, so far as it was in excess of the revenue of the year, should to the extent of one sixth be included in the accounts of the year and carried forward as a deficit against the revenue of next year, and that the remaining five sixths should be charged in equal proportions against the revenue of the next year and the four succeeding years, thus debiting next year (1901-2) with two sixths of the entire deficiency and each of the four following years with one sixth. The recommendation was discussed by the town council on May 13th and was adopted. The total expenditure, it is estimated, will be between £40 000 and £48 000.

Glasgow Royal Infirmary

At a meeting of the medical and surgical staff held on May 10th Mr. Hugh Brown was presented with an address on the occasion of his retiring from the chairmanship of the house committee which he has held for a term of 16 years. The presentation was made by the senior physician, Dr. John Dougall, and the senior surgeon, Mr. Henry E. Clark, C.M.G. In the course of his reply Mr. Brown referred to the proposed scheme of reconstruction and spoke hopefully of its speedy accomplishment. In regard to the site he was convinced that no better position could be found, unless the managers were prepared to purchase an estate on the outskirts of the city, and this would mean the removal of the infirmary from the centre of the busy manufacturing district for the surgical emergencies of which some such institution was a necessity. The chairman of the meeting was Mr. J. D Hedderwick who succeeds Mr. Brown as the chairman of the house committee. Two important professional positions in connexion with the infirmary are vacant—viz , a physicianship, vacant by the retirement of Dr Dougall, and the Professorship of Medicine in St. Mungo's College.

Bequests to Glasgow Institutions.

The trustees of the late Mr. Adam Teacher, acting in accordance with the will of that gentleman, have announced the following bequests Glasgow Royal Infirmary, £6500; Western Infirmary, £4800; Victoria Infirmary, £1700; Royal Hospital for Sick Children, and Glasgow Eye Infirmary, each £1200, Maternity Hospital, £800; Central Dispensary, Asylum for the Blind, Deaf and Dumb Institution, Lock Hospital, Cancer Hospital, each £600; Dental Hospital, £500; Samaritan Hospital, Ear Hospital and Dispensary, Hospital for Skin Diseases, and each of the Dorcas Societies of the three general infirmaries, each £300. Various convalescent homes and other charities also receive legacies. The total sum distributed amounts to £36,434.

Donations to the Paisley Hospital.

The directors of the Royal Alexandra Infirmary have received the following donations: (1) an additional donation of £1000 from Mrs Stewart Clark to the fund of £5000 instituted by her for the relief of incurables; (2) a sum of £736 19*s*. from Mr. James Coats to wipe out the deficit on the ordinary income and expenditure account of Dec. 31st last; and (3) a donation of £5000 from Mr. James Coats towards the reduction of the building fund debt.

May 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

National Maternity Hospital, Hollis-street, Dublin.

THE annual meeting of the friends and supporters of this hospital took place on May 10th in the Mansion House. On the motion of the Right Hon. the Lord Mayor the chair was taken by His Grace the Most Reverend Dr. Walsh, Roman Catholic Archbishop of Dublin. A very satisfactory report of the committee of the hospital was read by Mr. Andrew Horne, F R C P Irel., after which addresses were delivered by the Archbishop, Mr Brereton Barry, K C , Mr. Bodkin, K C , the Lord Mayor, Lieutenant-Colonel Ross of Bladensburg, C B , D L , and others.

Royal Medical Benevolent Fund Society of Ireland.

At the annual meeting of the subscribers to the Belfast or county Antrim branch of this society held in the Museum, Belfast, on May 8th, the President (Professor W. Whitla) being in the chair, it was reported that £190 17*s* 6*d*. (as compared with £75 1*s* 6*d* last year) had been contributed during the year—an increase due to the exertions of the President. There were 146 members of the medical profession in Belfast and 32 in the county districts who had subscribed, as against 67 and 20 respectively in the previous year A sum of £180 7*s* 7*d*., the largest contribution since 1876, had been remitted to the parent society in Dublin. 44 practitioners in Belfast and many of the country members of the profession did not subscribe On the other hand, the students of Queen's College have subscribed. Professor Whitla was re elected President for the ensuing year, Dr. H. L. McKisack secretary, Dr. R Purdon treasurer, and an ordinary committee and a collection committee were appointed.

The Ulster Medical Society.

The seventh meeting of the Ulster Medical Society was held in the Belfast Museum on May 9th, Dr. W. A McKeown, ex-President, being in the chair.—Dr. A Fullerton showed a case of marked Scoliosis in a boy, aged 13 years, and a case of Congenital Absence of the Radius and Thumb, with a radiogram of the same.—Mr. A. B. Mitchell showed (1) a patient on whom he had operated for Fractured Patella, with radiograms of the case taken shortly after the accident, after two weeks' treatment by extension, and after operation; (2) a simple form of Jacket for Spinal Caries; and (3) radiograms of a case of Congenital Absence of the Radius and of a case of Fracture of the Os Calcis treated by wiring.—Professor T. Sinclair showed radiograms of Fractures involving the Knee-joint treated by wire suturing.—Dr. Fullerton read a paper on "Tuberculous Lymphatic Glands."—Dr. W. Calwell showed a specimen of Malignant Disease of the Pancreas. He also exhibited a case of Tuberculous Skin Disease, and a boy with an Enlarged Spleen.—Interesting discussions followed these communications, some of the speakers limiting the wiring of a fractured patella to a separation of the fragments of more than three-quarters of an inch, while others thought the proper treatment of all fractures about joints was to wire the fragments.

Armagh County Asylum.

At the monthly meeting of the governors of the Armagh Asylum, held on May 13th, the half-yearly report of the auditor of the Irish Local Government Board was submitted which stated, among other matters, that the accounts for the half year were in a most unsatisfactory condition. There were no financial entries in the minute-book, and the financial statement book of receipts had not been confirmed by the committee for any month. No finance committee had been appointed and the bills bore no indication of having been examined or passed. Three of the treasurer's authorities were incorrect and the amounts paid by the treasurer in July and October exceeded the authorised totals by £100 and £7 respectively. The Lord Lieutenant's sanction to the increase of salary voted to the assistant medical officer had not been obtained. The amounts due by the late clerk, who had absconded, were £56 9*s.* 7*d*., and it was presumed that immediate steps would be taken to recover the sum from his sureties. The committee had evidently disregarded the suggestion of the auditor to discontinue the monthly luncheon, and there was, therefore, no course open to him but to surcharge the amounts thus illegally placed upon the ratepayers. It was impossible to ascertain the full amount, but £5 17*s.* 8*d.*, the amount paid for wine and extras, would be disallowed. It was but right to say that many members of the committee were opposed to the luncheons and did not attend them. Many other irregularities were mentioned and the report went on to say that for this state of affairs the responsibility rested not only on the medical superintendent but also on the committee, and it would be necessary in future that the former should exercise the intelligent supervision over the books which was required by the regulations of the asylum accounts order, and that the committee should, as a committee or as a body, satisfy themselves that the officers were discharging the duties for which they were paid.

Small-pox in Belfast.

Up to the present time there have been five cases of small-pox in Belfast with one death and one suspected case.

May 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sanatoria for Tuberculous Patients.

AT the meeting of the Academy of Medicine held on April 30th M. Lemoine, speaking both in his own name and also on behalf of his colleague M. Carrière, said that in France after too long a period of apathy medical opinion was following with undue rapidity the course taken by the Germans, without being sure even yet that the sanatorium system was the only trustworthy method of treating tuberculosis. To cure this terrible disease, which caused the death of 150,000 persons in France every year, it was necessary above all things to remove the patient from the conditions under which he had contracted tuberculosis—these being, in the first place, overwork, intemperance, and overcrowding in towns; and, in the second place, organic taints, inherited disease syphilis, intemperance of parents, &c. Tuberculous patients living an easy life, supplied with unlimited food, and spending their time in the open air, were undergoing the proper treatment for their disease, and they could combine all these conditions without crowding into sanatoria. The majority of the tuberculous patients sent to renowned establishments in foreign countries came back very little improved, and what progress they had made was rapidly lost on returning to their homes. Then there were interminable and costly "seasons." The majority of these establishments were excellent properties in a financial sense. M. Lemoine drew a somewhat unflattering picture of certain sanatoria. In one sanatorium some of the patients contracted pneumonia owing to the cold; others, deprived of the company of their families and abruptly withdrawn from an active life, fell into a deplorable state of melancholy which was encouraged by the spectacle presented by their fellow patients. In another the patients gave themselves up to all sorts of excesses with the connivance of the managing officials. M. Lemoine has arrived at the conclusion that in any place where patients can live under the hygienic conditions mentioned above the treatment of tuberculosis may be carried out as successfully as in sanatoria, or indeed even more so. The proposal of M. Brunon of Rouen to transform into sanatoria the wards of communal infirmaries or even peasants' cottages in suitable situations was an excellent one. On the other hand, the course to which the State seemed to be committing itself, in the construction of huge establishments on the plan of that at Angicourt was costly out of all proportion to the results. To treat in this way the 300,000 tuberculous subjects in France would require, at 6000 francs (£240) per bed, an original outlay of 1,800,000,000 francs (£72 000 000) and an annual expenditure of 328,000,000 francs (£13,120,000). With a vastly smaller sum it would be possible to carry out efficacious measures of prophylaxis and to obtain much more certain results in the way of cure by, in the first place, discouraging intemperance, by admitting patients freely into the existing establishments in all country places, only making necessary structural alterations and placing them under the control of the local medical men, and, finally, by enlarging the field of action of the Poor-law medical officers with a view to the repression of the disease.

The Use of Blisters in Diagnosis.

M. Roger and M. Josué described to the Société Médicale des Hôpitaux on May 3rd a truly original diagnostic method based upon the microscopical examination of the serous fluid contained in the vesicle which rises when a blister is applied. This fluid always holds in suspension a great number of cells. In the normal individual a large proportion (25·19 per cent.) of polynuclear eosinophile cells is found. In persons suffering from infectious complaints these cells are fewer in number or they may be completely absent, and they reappear if the organism prevails over the infection. The examination of blister fluid, therefore, supplies valuable information as to the intensity of the impregnation of the system by infectious toxins and as to the action of the blood-forming organs. These effects depend on the influence exerted by microbial toxins on the bone marrow. When acted on by these poisons bone marrow gives rise to polynuclear neutrophile cells and is consequently unable to supply eosinophile cells. But the application of a blister creates a tendency to the production of eosinophile cells, and the examination of the effused fluid shows to what extent the bone marrow is capable of forming these elements. In ordinary chronic tuberculosis the polynuclear neutrophile cells preponderate greatly, the eosinophile cells are either very few or altogether absent, and the proportions of the other cells are somewhat variable. The cells have often a peculiar appearance, being swollen as if distended with fluid and much larger than in normal individuals. This condition of the cellular elements, without being confined to tuberculosis, is more marked in it than in other infections. In one case in which the condition was very evident it led the observers to the discovery of the existence of latent tuberculosis. In a case of fibroid phthisis M. Roger and M. Josué found 3 2 per cent. of eosinophile cells. In a tuberculous patient at the very beginning of the disease and in general good health there were 7 8 per cent. of eosinophile cells. In two cases of acute sero-fibrinous pleurisy—i.e., in localised tuberculosis of the pleura—tending towards recovery there were 13 7 and 18 per cent. of eosinophile cells. In erysipelas, mumps, acute tonsillitis, polymorphous erythema, and broncho-pneumonia they have seen the number of the eosinophile cells vary from 0 to 2 or 3 per cent., according to the stage of the disease and the tendency to recovery. By this method of diagnosis very slight pathological changes could be recognised; it gave information as to the state of the blood-forming organs and as to the degree in which certain toxins might be present in the organism.

Necropsies in the Army, the Navy, and the Colonies.

In the army the rules of the service relative to necropsies give the medical officer the right of making them or of having them made under his direction whenever he considers them to be necessary. In practice necropsies are only made (1) when death has been sudden and unexpected; (2) when it has occurred out of hospital either in town or in barracks; and (3) when it has been the result of accident or is ascribed to ill-usage or neglect. The formal report of these necropsies is taken into consideration at the inquiry which in these cases is always held by the military authorities. In the navy the general idea is the same, but in addition, since many sailors are married, necropsies are made for the purpose of establishing, if necessary, the claims of the widows and orphans to a pension. According to M. Grandjux, who has just made a communication on this subject to the Society of Legal Medicine, a recent circular of the Minister of Marine orders that post-mortem examinations shall be made on the bodies of all sailors who have died in hospital. This decision has been come to in consequence of a family protesting because a pension had been refused them on the ground that the Conseil de Santé had not been able to obtain a necropsy as the relatives had claimed the body immediately after death. For vessels at sea a decision of March 16th, 1899, orders that unless there is some insurmountable obstacle necropsies shall be made in the cases of all men dying from ill-defined diseases, always with the view of establishing the claims of widows and orphans to a pension when death has been due to causes connected with the duties of the deceased. The same conditions hold good in the colonies. Speaking generally, says M. Grandjux, in the army, the navy, and the colonies, necropsies on the one hand by fixing responsibility protect individuals against ill-usage and neglect, and on the other hand for the families of the deceased they serve to establish a right to pensions. Necropsies are therefore a means of social defence and protection.

Arsenic in Beer.

At its last meeting the Conseil d'Hygiène et de Salubrité of the Seine adopted the following motion:—

> Having regard to the cases of poisoning which have occurred in England, and especially in Manchester, although arsenic has not yet been found in imported beer in Paris, the Council requests the Prefect of Police to call the attention of the responsible Ministers to the possibility that foreign beer, syrup, confectionery, &c., imported into France may contain unwholesome substances or even poisons.

May 14th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Battle of the Clubs in Leipsic.

THE strike of the medical officers of the Leipsic sick club has now come to an end through the mediation of the municipal authorities. It has been agreed: (1) that the committee of the medical officers' union shall consist exclusively of members engaged in club practice and not of other medical men; (2) that a permanent court of arbitration shall be created, consisting of members of the Leipsic medical chamber and members of the committee of the club, presided over by the chief medical officer of the city of Leipsic, and empowered to settle any dispute arising between the club and its medical officers; and (3) that the club shall maintain the free choice system and shall not issue orders direct to the medical officers without reference to their committee. Both parties have accepted these conditions and the strained relations so unpleasant to both the medical officers and the club members have now happily disappeared. It is, however, an advantage that [illegible] vn by these events to the state [illegible] many and especially to club [illegible] that in the forthcoming legislation relative to sick clubs the interests of the medical profession will be regarded more than has hitherto been the case.

Pharmaceutical Chemists and Sick Clubs.

A dispute of a different nature and one in which the medical profession is only concerned indirectly deserves to be noticed as it affords a good example of the aggressive policy pursued by the sick clubs. The scene of the present conflict is in Berlin, the opposing forces being the majority of the clubs on one side and the Berlin licensed pharmacies on the other. To make the position of affairs intelligible it will be necessary to give some account of the German law relative to pharmaceutical businesses. The number of pharmacies (Apotheken) is limited for every town by the authorities and is increased only in proportion to the growth of the population. When a new pharmacy is to be established in a district of any town candidates, who of course must be qualified pharmaceutical chemists (Apotheker) are invited to make application to the local authority, and the licence is, as a rule, given according to seniority. Formerly, the licence could be sold at once to any other qualified pharmaceutical chemist, but this is no longer possible under the law. When the licence has been granted the holder is bound to establish the pharmacy in the district assigned to him within a certain time and to conduct it himself He cannot sell it, but if at any time he wishes to retire he has to give back his licence which is then granted to another applicant. If he dies, the business may, however, be conducted on behalf of the widow and children by an authorised representative for 10 years. The licensed pharmacies are all under Government control and the official requirements as to the state of the premises, the quality of the drugs, and the laboratory arrangements must be strictly observed. A good deal of money is therefore required for establishing a pharmacy and many of the licensees, especially in the larger towns, where house rent is very high, have to borrow money and to pay heavy interest, so that their financial position may from the beginning be rather precarious. In addition to the licensed pharmacies there exist, especially in the larger towns, drug-stores which are not under special Government control, but are subject only to the general laws affecting workshops and trades. Their number is therefore not subject to any limitation and no licence is required, but they must not sell poisons, neither may they compound medicines. Their business consists only in the so-called Handverkauf (sale of simple remedies such as may be purchased without the written prescription of a medical man). To return to the above-mentioned conflict between the clubs and the pharmacies it has to be explained that hitherto it has been the rule that the club members were allowed to order their medicines in any licensed pharmacy in Berlin. When they showed a prescription written by a medical officer of their club on a voucher with the club stamp they had nothing to pay, as the druggist's charges for all drugs, medicine, &c., were settled quarterly at the club offices. Medicine was thus obtained on credit and other facilities which it would take too long to explain were granted to the club members by the pharmacies. The clubs, on the other hand, agreed to instruct their members to order everything from the licensed pharmacies even those compounds which were obtainable in ordinary drug-stores. This state of things had gone on as long as sick clubs had existed in Berlin, but some time ago a movement was set on foot which was intended to have the effect of withdrawing some of the custom of the clubs from the pharmacies It was alleged that the prices charged by the pharmacies, although fixed officially by the Government, were much too high, that great profits were exacted even from the poorer classes, and that a discount of at least 10 per cent. ought to be granted to the clubs. The Association of Proprietors of Licensed Pharmacies declined to allow any abatement of their ordinary prices and the great majority of the Berlin clubs then decided to boycott the pharmacies so far as the law permitted, the members being instructed to deal as much as possible with the drug stores. For obtaining poisonous substances, and specially compounded medicines which could only be sold by licensed pharmacies, the committee of the united clubs selected out of the 200 pharmacies in Berlin and its suburbs 60 with which club members were authorised to deal to the exclusion of the rest In this way the clubs hoped that disunion would arise among the licensees and that their resistance would be broken The licensed pharmaceutical chemists had, however, previously to the announcement of the boycott agreed among themselves not to enter into any negotiations with the clubs without the consent of the pharmaceutists' union and to pay a fine in the event of failing to keep their agreement. Moreover, the money paid by the clubs to the 60 selected pharmacies was to be divided according to the previous year's income among all the 200 pharmacies which were open. The pharmaceutists' union also issued public notices to the effect (1) that the proceedings of the clubs were not in the interest of the members who, when they required medicine, instead of applying at the nearest pharmacy, might have to walk at night for half an hour before coming to one of the selected pharmacies; (2) that the drugs kept in the drug-stores, not being inspected by the district medical officer as in the pharmacies, were not of reliable quality; and (3) that the drug-stores being subject to the general trade laws must be closed on Sundays and from 9 P.M. to 7 A.M., whilst the pharmacies were open every day and medicines could also be obtained there at night. The conflict between the pharmacies and the clubs is still going on, to the great inconvenience of the club medical officers, as the system to be followed in giving prescriptions is now more complicated than before. There is, however, no doubt that the boycott will very soon be withdrawn, firstly because the club patients will not willingly submit to all the arrangements connected with it, and secondly because it will be useless, owing to the strong organisation of the licensed pharmacies. These circumstances are now described at length because they are of more than mere local interest, illustrating as they do the present state of club practice, a question of much importance to the medical profession in Germany. If the organisation of the medical profession were made as strong as that of the pharmaceutical profession things would become better than they are now.

May 13th.

Obituary.

JOHN CAVAFY, M.D., F.R.C.P. LOND.

DR. CAVAFY, for many years one of the physicians to St. George's Hospital, died suddenly in London on April 28th. He was born on June 12th, 1837; his parents, George John and Mary Cavafy, being of Greek descent, and he received his early education at Brighton and University College, London. He was destined for business and for four years worked in his father's office, but his tastes appeared to have another direction, for from boyhood he always showed great interest in natural history, especially botany and ornithology. Ultimately he determined to relinquish the business career on which he had entered and to devote himself to medicine, for which purpose he entered St. George's Hospital as a student in 1861, being then, of course, rather older than the majority of his classmates. In 1867 he took the M.B. degree at London University, on which occasion he had a place in the first class, and in 1869 he became M.D. In 1868 he was admitted a Member of the Royal College of Physicians of London and in 1876 he was elected a Fellow. At St George's Hospital he held a number of appointments, being at first demonstrator in histology and afterwards lecturer in comparative anatomy, medical registrar, and lecturer on physiology and medicine. In 1875 he was assistant physician and in 1882 he became full physician. He was also physician to the skin department at St. George's Hospital, and during the International Medical Congress held in London in 1881 he was honorary secretary to the section of skin diseases. His other appointments included those of examiner in medicine in London University and to the Royal College of Physicians of London, consulting physician to St. Peter's Home, Kilburn visiting physician to the Atkinson-Morley Convalescent Home, and physician to the Victoria Hospital for Children. In 1896 he suffered from enteric fever which permanently impaired his health, and in 1898 he recognised that his best course would be to resign his duties at St. George's Hospital, of which he was then senior physician, and to leave London where he had long resided in Upper Berkeley-street. He was accordingly elected consulting physician to St. George's Hospital and went to reside at Hove, Sussex. Dr. Cavafy married Marigo, the youngest daughter of Mr. Antonio Ralli, and has left one daughter. He was the author of numerous contributions to St. George's Hospital Reports and the Transactions of various societies. In THE LANCET he published articles on Urticaria Pigmentosa and on the Education of the General Practitioner in 1880, and a description of a case of Yellow Atrophy of the Liver in 1897.

A medical friend of Dr. Cavafy, an intimate acquaintance of more than 40 years' standing, writes: "In Dr. Cavafy's death the profession has sustained a heavy loss which will be felt deeply by everyone with whom he came into contact; most deeply by those who knew him best. From the moment he joined the medical school at St. George's Hospital it was felt by all connected with it that a man had come among us of exceptional ability with very varied attainments. It was immediately recognised by his contemporaries that John Cavafy was a man to be appealed to on subjects outside the profession and to be trusted whenever he expressed his opinion. Having served for a time as medical registrar at St George's and as curator at the Westminster Hospital he became assistant physician at the former, and it was then that the opportunity was afforded him of displaying his power of observation and his special skill in imparting knowledge. Always clear, always emphatic, very rarely dogmatic, he had few equals as a teacher of medicine. Remarkable accuracy characterised all his work. Whether it was a chemical analysis, whether it was the compilation of a lecture, or the correction of a proof,—all was done with the same scrupulous exactness. He was a really good linguist, and it was due chiefly to this that in his knowledge of medical literature, both English and foreign, he was superior to most of the physicians of his time. To his talents as an artist some very beautiful water-colour drawings in the museum at St. George's bear ample testimony. It was ever a matter of regret among his friends that he devoted so little of his time to his brush. Dr. Cavafy was an excellent musician, he possessed a most delicate ear and a highly retentive memory. But apart from these varied attainments he will be best remembered for the affectionate nature which endeared him to his friends, and for his intense aversion to anything 'snobbish' or underhand. These characteristics influenced his every action in life. Courteous and genial to all, he was always indulgent to the faults of others; he had no harsh word for the conduct of anyone, unless it were tainted with injustice or dishonour. With intellectual qualities of the highest order, with an infinite sense of humour, with a keen and ready wit, he was a most delightful companion. He was a learned physician; he was a just and honourable man. No man ever made firmer friends or fewer foes."

CHARLES HITCHMAN BRADDON, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

THE death of Dr. C. H. Braddon of Manchester, at the age of 64 years, has caused widespread regret among his numerous friends. Dr. Braddon was the eldest son of the late Charles Braddon, surgeon, of Upton-on-Severn. He received his medical education at St. Thomas's Hospital, where he held the post of resident accoucheur. He then became assistant medical officer in the Derby County Asylum, from which place he went to Manchester. In 1862 he was appointed resident physician's assistant to the Manchester Royal Infirmary. In December of the same year he became assistant medical officer of the Bridge-street Workhouse. In 1864 he was appointed medical officer of the Cathedral district. In these offices he acquired that intimate knowledge of fevers which qualified him to fill so well the position of chairman of the Hospitals Sub-committee of the corporation. About this time he started in practice in Cheetham-hill, and in 1866 he was appointed surgeon to the Strangeways Prison, a position which he held for more than 20 years. For many years he acted as visiting physician to the Clifton Asylum. In 1872 he became secretary and treasurer for the Manchester district to the Royal Benevolent College, Epsom, and worked strenuously to obtain fresh adherents to that admirable institution. Since its inception he acted as treasurer of the Manchester Clinical Society of which he had also been chairman. For many years he was secretary to the Manchester Medico-Ethical Society. He also acted as medical officer to the Bethesda Home for Crippled Children, in which he took a deep interest. Recently he was elected chairman of the Manchester Medical Guild. His public services were by no means entirely of a professional character. In 1892 he was elected to the City Council as one of the representatives of Cheetham Ward, a position which since that time he has retained with the goodwill of all. He served on three committees, and in 1896 became chairman of the Hospitals Sub-Committee, an office which he filled with assiduity and felicity. The establishment of administrative measures in Manchester for the prevention of tuberculosis was in no small degree owing to his sympathetic support. In politics he was a Conservative and he acted as chairman of the Conservative Association in Crumpsall. He was a Churchman and was churchwarden at St. Luke's for many years, taking much interest in the church and in the schools. He was a Justice of the Peace for the county of Lancaster. Very popular in his profession, in private life he had many friends. Genial, even-tempered, kind-hearted, and just, he was at the same time a man both of decision and judgment. Careful and sparing of speech, his remarks carried weight and advanced the object which he supported. He has left a widow and grown-up family.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. S. Lamanski of St. Petersburg, a physiologist and physicist whose published papers deal especially with electrical fluorescent phenomena in physiology. He was 60 years of age, and as a student had worked under Rudolf Leuckart, Helmholtz, and other distinguished physiologists.—Dr. H. Gosse, Professor of Forensic Medicine in the University of Geneva.—Dr. W. von Heinecke, Professor of Clinical Surgery in Erlangen.—Dr. von Iterson, Professor of Clinical Surgery in Leyden.—Dr. Karl Laufenauer, Professor of Psychiatry and Neurology in Budapest.—Dr. H. Napias, Director of the Assistance Publique of Paris.—Dr. F. Wayland Abbott, a well-known New York ophthalmic surgeon.

Medical News.

AT the meeting of the Cheltenham Town Council held on May 6th it was resolved to increase the salary of Dr. J. H. Garrett, medical officer of health, from £500 to £600, on account of his excellent work during the past nine years.

BEQUESTS TO MEDICAL CHARITIES.—Mr. T. E. Exley, who died recently at Trowbridge, has bequeathed the following legacies:—Bristol Royal Infirmary, £1000; Bristol General Hospital, £1000; and the Trowbridge Cottage Hospital, £500.

MONUMENT TO PROFESSOR HUXLEY.—It is proposed to erect at Ealing (the place of his birth) a memorial to Professor Huxley. The form it will take is not at present decided upon. Subscriptions to the fund may be forwarded to Mr. T. Simpson, Fennymere, Castle Bar, Ealing.

BRISTOL MEDICAL CHARITIES.—The late Miss Mary Cannington of Bristol bequeathed £10,000 in consols to the Bristol Royal Infirmary, £5000 to the Bristol General Hospital, and £500 each to the Bristol Dispensary and the Bristol Eye Hospital.

NATIONAL SANATORIUM FOR CONSUMPTION, BOURNEMOUTH (OPEN-AIR TREATMENT).—The annual general meeting of governors of this institution was held in London on May 9th at the Westminster Palace Hotel, the Earl of Eldon, the President, occupying the chair. The annual report of the committee for the year 1900 was placed before the governors, the statement of accounts showing a balance in hand of £122. Special measures were considered for meeting the increase in necessary annual expenses incurred by the efficient carrying on of the open-air treatment of patients, which had been successfully adopted for some time past. Measures having been also discussed for obtaining increased funds to carry out the proposed extension of the building, it was resolved that a further appeal for donations and subscriptions should be made to the public. The following resolution was also unanimously passed:—

> That the humble petition of the governors and committee of this charity be placed before His Majesty the King for his gracious continuance of the Royal patronage formerly granted by Her late Majesty Queen Victoria since the year 1869.

THE ROYAL INSTITUTION.—On Friday evening, May 10th, at the Royal Institution, Professor J. C. Bose gave a lecture on "The Response of Inorganic Matter to Mechanical and Electrical Stimulus." Referring to the production of a current of electricity in the optic nerve when the stimulus of light was applied to the eye, he said that although the electric response had been considered to be a delicate sign of life, as a matter of fact inorganic bodies also responded to similar tests. Both the form of response and the condition under which it was manifested showed a remarkable similarity between living and inorganic matter. This argument Professor Bose sustained by a number of statements and he showed an artificial retina which was sensitive to light and to electricity.

UNIVERSITY OF CAMBRIDGE.—H. C. Haslam, M.A., M.B., B.C., of Gonville and Caius College, has been elected to a John Lucas Walker studentship in pathology.—Dr. Sladen, who received permission to leave his work in Cambridge to join his mobilised militia battalion for service in Ashanti, and who has now returned, has been reinstated as a second student.—At the congregation on May 9th the following medical and surgical degrees were conferred:—M.D.: F. M. Pope, M.A., Magdalene College; A. R. Paterson, M.A., Emmanuel College; and A. B. Green, M.A., Downing College. B.C.: A. E. Hodder, King's; H. Gordon-Smith, C. H. Miller, G. H. Orton, and J. C. S. Rashleigh, Trinity; J. A. Glover, St. John's; C. H. Glenn, Pembroke; R. F. Williams, Caius; and A. W. Greig, Jesus.

PREVENTION OF TUBERCULOSIS.—The annual meeting of the Devon and Cornwall branch of the Association for the Prevention of Consumption and other forms of Tuberculosis was held at Plymouth on May 9th under the presidency of the Earl of Mount-Edgcumbe. There were also present Surgeon General Evatt, Dr. Lionel Weatherly, Dr. E. L. Fox, Mr. P. Swain, Dr. H. W. Webber, Mr. T. Bulteel, Mr. C. Wills, and Dr. F. Bushnell. The report alluded to the smallness of the income of the branch, the balance over expenditure being only £31, and stated that in order to carry out the work satisfactorily a larger income was necessary. It was stated that over 1000 deaths had occurred from consumption in the two counties during the past year, a decrease of 100 as compared with the preceding 12 months, and it is estimated that about 3000 are suffering from the disease. The committee advocate the establishment of a bacteriological laboratory for the early diagnosis of consumption, a home for advanced cases, and a sanatorium.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the Royal College of Physicians of Edinburgh was held on May 7th, Dr. Fraser (the President) being in the chair.—The President reported that together with the Vice President and the Treasurer he had been received by His Majesty the King who graciously accepted the loyal address of the College and handed to him the following reply which the President read to the Fellows standing:—

> [illegible] warmest sympathy and support."

Lewis Campbell Bruce, M.D., M.R.C.P. Edin., and Claude Buchanan Ker, M.D., M.R.C.P. Edin., were admitted by ballot to the Fellowship of the College.—On a ballot the following candidates were admitted to the Membership of the College—viz.: David Duncan Main, L.R.C.P. & S. E., Hangchow; John Jackson Berry, M.D., Manchester; John Malcolm Farquharson, M.B., C.M. Edin., Edinburgh; Thomas Manners-Smith, M.B., B.C. Cantab.; Francis Herbert Aylen Clayton, M.D. Edin.; and James Garvie McNaughton, M.D. Edin.—The Registrar reported that since the last quarterly meeting 32 persons had obtained the Licence of the College by examination.—The College approved of the address of congratulation to the University of Glasgow on the occasion of the celebration of the ninth jubilee of its existence.—On the nomination of the President the following delegates were elected to represent the College at the British Congress on Tuberculosis—viz.: the President, the Vice President (Dr. James Andrew), and Dr. G. A. Gibson and Dr. R. W. Philip.—By vote of the College two Licentiates were expelled from the College and deprived of their Licences, and a third was deprived *sine die* of all his rights and privileges as a Licentiate of the College.

The City Coroner's Superannuation.—The Corporation of London has granted Mr. S F. Langham on his retiring from the office of coroner an allowance of £600 a year.

Presentation to a Medical Man.—Mr. Thomas Carson Fisher, M.D. Dub, of Bowral, New South Wales, on his leaving that town after a residence there of 11 years, has been presented with an illuminated address, a purse of sovereigns, and a travelling bag.

The Stockport Isolation Hospital.—The alleged mismanagement of the Isolation Hospital in Dialstone-lane was discussed by the Stockport Town Council recently. The discussion did not make quite clear whether the patients were kept short of food as was alleged, but the acrimonious feeling which it is evident exists between some of the parties concerned is more than regrettable.

Recovery of Medical Fees.—At the Exeter Police court on May 7th Mr J. Somer and Dr. J. W. Sandoe, surgeons, of Broadclyst, Devon, sued the executors of a deceased lady for £7 17*s.* for professional services. For the defence the solicitor pleaded the executors' "right of preference and retainer," but his honour Judge Woodfall gave judgment for the plaintiffs.

Unsuitable Food.—At an inquest held in Bristol on May 7th upon the body of an infant, aged seven months, who had died suddenly, medical evidence showed that death resulted from convulsions, probably caused by some fried fish which was discovered in the stomach at the post-mortem examination. The jury returned a verdict accordingly.

Literary Intelligence.—We are informed that Dr. G. Vivian Poore's volume of "Essays on Rural Hygiene," first published by Messrs. Longman in 1893, has just been issued at Wiesbaden in a German translation under the title of "Essays uber Hygiene auf dem Lande." Dr. Eugen Farkas of Budapest, who was engaged on a Hungarian version of the same work, has unfortunately died before completing the translation.

Unsatisfactory Vaccination.—At the meeting of the Barton Regis (Bristol) Board of Guardians held on May 10th it was decided to support the action of the Portsmouth Union and petition the Local Government Board that for children vaccinated privately the operation should be of the same standard as for those vaccinated publicly. The chairman (Mr Shipley) said that the way in which some vaccinations were performed in one place was a complete farce

French Hospital and Dispensary.—The thirty-third annual dinner in aid of the funds of this institution was held on May 11th at the Hotel Cecil, His Excellency M. Paul Cambon, the French Ambassador, being in the chair, supported by the Lord Mayor and Sheriffs and many members of the *corps diplomatique.* After the toast to M Loubet, President of the French Republic, had been drunk the Chairman proposed that of the King and the Royal Family, mentioning that His Majesty had been graciously pleased to continue the patronage which Her late Majesty had extended to the French Hospital. In proposing the toast of the Founders, Benefactors, and Supporters of the hospital the Chairman said he was pleased to see so many representatives of the diplomatic body present, and after thanking the Lord Mayor for his support he congratulated Sir William MacCormac on his recent promotion in the Legion of Honour. M. Metaxas, the Greek Minister, responded on behalf of the guests and spoke in terms of commendation of the services rendered to the hospital by the secretary, M. Pontdepeyre. He was followed by the Lord Mayor who pointed out that the hospital, which was founded in 1867 to accommodate 16 patients, now had accommodation for 70, it having been rebuilt under very favourable conditions. Dr. Ogilvie responded on behalf of the medical staff in a humorous speech, delivered partly in English and partly in French. The musical programme, under the direction of Signor Tito Mattei, was unusually well filled and well rendered by Miss Percival Allen, M. H. Leoni, Miss Florence Venning, Master Bernard Crook, and other vocalists.

Cost of Vaccination.—At the meeting of the Penzance Board of Guardians held on May 9th some discussion took place upon the amount of the vaccination fees It was stated that in 1898 the fees amounted to £108 and in 1900 to £377. Some members considered that it would be more economical to obtain a medical officer to devote the whole of his time to the duties of the office, but on the clerk explaining that a scale of fees had been fixed by law and that the guardians had adopted the minimum the matter dropped.

Llandaff and Dinas Powis Rural District.—The annual report of Dr. R. Prichard, medical officer of health of the Llandaff and Dinas Powis Rural District, states that in the district (which is one of the largest in the kingdom, having an area of nearly 102 square miles, with a population of 22,400) the births during 1900 numbered 658, equal to a rate of 31 67 per 1000. 332 deaths were registered, giving a death-rate of 14·6 per 1000. The average age at death was 36¼ years. The infantile deaths were at the rate of 3 76 per 1000, and in the proportion of 118 per 1000 births.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Gases from Alkali Works.

There has been introduced into the House of Lords a short measure to strengthen the law with regard to the pollution of the atmosphere by acid gases from alkali and other chemical works.

Lunacy Bill for Ireland.

The Bill introduced by the Government to amend the law in Ireland relating to lunatics embodies several provisions of the law in England with regard to this subject. For instance, it proposes that the Lord Lieutenant may, in addition to his power of absolute discharge, also discharge a criminal lunatic conditionally. In the present state of the law in Ireland a criminal lunatic can only be released without condition. Another provision of the Bill deals with the ill treatment of lunatics, and a third with the expenses incurred in the care and treatment of criminal and dangerous lunatics.

HOUSE OF COMMONS.

THURSDAY, MAY 9TH.

Medical Provision in the West of Ireland.

Mr. DUFFY asked the Chief Secretary to the Lord Lieutenant of Ireland (1) whether he had any further news to communicate to the House respecting the spread of fever in the Arran Islands; (2) whether he was aware that the medical inspector of health fell a victim to the malady and was left for an entire week without a medical attendant until he died; whether any complaints had reached him respecting the neglect shown to this gentle [illegible] ot in the execution of his duty, and wheth [illegible] was temporarily appointed or volunteered to look after and discharge his duties during his illness; and (3) whether, in view of all the circumstances, he will cause an inquiry to be made into the entire matter.—The ATTORNEY-GENERAL for IRELAND replied to the question, saying that the latest report from the acting medical officer of health, received on April 25th, was to the effect that the epidemic had passed away. As regards the late medical officer of health, it appeared that although he had recovered from fever he had since succumbed to pneumonia. He had no information as to the other matters referred to in the second paragraph When the late medical officer fell ill the islands were temporarily placed in charge of Mr. M. F. Lyden, the medical officer of Galway No 1 Dispensary District, and a medical gentleman from Dublin had since been appointed to the vacant office There did not appear to be any necessity for an inquiry as suggested at the conclusion of the question.

Rabies in Dogs.

Mr. HANBURY, interrogated as to the effect of the dog regulations of the Board of Agriculture, said that in 1895 there were 672 cases of rabies and in 1898 there were 438, while after the regulations in 1900 there were six cases, and in 1901 up to May 4th there was only one case.

FRIDAY, MAY 10TH.

Scarlet Fever in the Forest Gate Schools

Dr. FARQUHARSON asked the President of the Local Government Board whether he could say how many children had suffered from scarlet fever during 1900 and 1901 at the Forest Gate Poor-law schools?—Mr. LONG replied that he understood that there was no case of scarlet fever during 1900 and 13 cases during the present year down to May 4th.

MONDAY, MAY 13TH.

The Disposal of Arsenicated Glucose.

Mr. CHANNING asked the President of the Local Government Board whether his attention had been called to the evidence given by Mr. Williamson, representative of Messrs. Bostock, that no less than 700 tons of glucose and invert sugar supposed to be contaminated with arsenic were now in the possession of the liquidators of the company, and whether, in the interest of the creditors, he could and would take steps to prevent any disposal of this contaminated material to the risk of the public health.—Mr. LONG replied: I am aware of the evidence given by Mr. Williamson on this subject before the Royal Commission. I understand, however, that he has assured the Commission that none of the material referred to will be disposed of without notice to them. I also understand that the Commission have suggested that before the material is disposed of in any way it should be so dealt with by the [illegible] as to render its employment [illegible] dators have under- [illegible] r may rest assured [illegible]

The Medical Register at Irish Petty Sessions.

Mr. MCFADDEN asked the Attorney-General for Ireland whether he was aware that the Castle authorities had discontinued the issue of the Medical Register for the use of the petty sessions courts in Ireland, and whether, considering the usefulness of the former practice to the officials, the issue would be revived.—Mr. ATKINSON replied: The gratuitous supply of this publication to courts of petty sessions in Ireland has been discontinued on the advice of the registrar of petty sessions clerks. It is not proposed to revert to the former practice.

TUESDAY, MAY 14TH.

Reserve Officers of the Royal Army Medical Corps.

Mr. MACNEILL asked the Secretary of State for War whether he could explain why, while under the provisions of the army orders army *reserve* officers [illegible] of their rank in the [illegible] but were eligible for [illegible] reserve office [illegible] within the [illegible] general list [illegible] that the pri [illegible] was likewise [illegible] Army Medic [illegible] officers shou [illegible] medical staff [illegible] Army List.

Netley Hospital Case.

Mr. J. P. FARRELL asked the Secretary of State for War whether he was aware that evidence was submitted in the course of the inquiry into the alleged ill-treatment of Private M. Lee, late of the Imperial Yeomanry, in Netley Hospital, to support the charge that the probationer in charge of the ward said that when he had done with him he would have no more fits; whether he was aware that Lee's bodily health had been seriously injured by the treatment which he had received; and whether he could [illegible] awarded to the offending official.—[illegible] *does not appear to show that the* [illegible] Private Lee used the expression [illegible] health has been seriously injured. But the treatment, with whatever good intentions applied, is not sustained as applicable to the case by high authorities, and the surgeon's experience does not justify us in continuing his services.—Mr. FARRELL: Has the right hon. gentleman consulted the eminent medical authority he referred to last week?—Mr. BRODRICK: It is the advice of the eminent specialist whom I consulted which has forced me to decide that we cannot continue the services of the surgeon.

Sewage and Drainage.

At this sitting of the House Sir WALTER FOSTER formally introduced a Bill to enable local authorities to deal separately with the sewage and drainage of their districts.

ROYAL COMMISSION ON ARSENICAL POISONING.

FRIDAY, MAY 10TH.

THE Royal Commission on Arsenical Poisoning, consisting of Lord Kelvin (Chairman), Sir William S. Church, Sir William Hart-Dyke, M.P., Professor Thorpe, Dr. B. A. Whitelegge, and Mr. Cosmo Bonsor, with Dr. G. S. Buchanan as secretary, met again to-day in the Westminster Palace Hotel, London, and proceeded with the examination of witnesses.

Mr. [illegible] said th [illegible] insteac [illegible] law no [illegible]

Sir [illegible] said th [illegible] cross-e [illegible] not de [illegible]

Mr. [illegible] a cons [illegible] with a [illegible] Part c [illegible] return- [illegible] quanti [illegible] dispos- [illegible] was o [illegible] He believed that it was the intention of the liquidators to go on selling the stock in this or some other way, and he was not aware that they proposed to take any further safeguard against mischance.

Sir WILLIAM CHURCH: We know that some of your sugars were used by children for making toffee with bad results.

WITNESS: We were not aware of that.

SIR WILLIAM CHURCH: And in the same way they might take this contaminated sugar from, say, a leather-dresser's store.

WITNESS: We did not think it necessary to suggest any safeguard nor do I know of any safeguard we could adopt. The sugar is not intended for food.

[illegible] s poisonous substance [illegible] g into food. [illegible] ied or made so dis- [illegible] to be used in food? [illegible] ve by the introduction of materials which would not affect its use for commercial purposes.

WITNESS: *If that could be done it might be done.*

Sir WILLIAM CHURCH: I do not think it is the part of the Com- [illegible] of the [illegible] d with [illegible] ions as [illegible] ir consideration.

Dr. WHITELEGGE: Has the medical officer of health of Garston been consulted?

WITNESS: He has not.

Sir WILLIAM CHURCH: I put it to you that the Commission ought to be informed what steps it is proposed to take.

WITNESS: I will see that you are informed.

Sir WILLIAM CHURCH: And the destination of each consignment?

WITNESS: Yes, I will see that that is done.

Mr. E. G. FRANCIS, manager of the Mambré Saccharine Company, [illegible] of [illegible] id, [illegible] be [illegible] the [illegible] his [illegible] contaminated if proper care were taken in its preparation. *He* was aware that there was a prejudice against the use of pyrites acid, and for that reason he had tried many brimstone acids, but he had never found one as pure as the pyrites acid used by the company. In each case the company gave a guarantee that their goods were absolutely free from arsenic, and he saw no objection to this *guarantee being tested by some Government department.*

Mr. RUDOLPH FREDERICK WAHL, managing director of the Nord Deutsche Kartoffel-Mehl Fabrik, Limited, of Custrin in Prussia, was the next witness, and in the course of his examination *he said* that his company manufactured purified starch or farina, dextrine, and glucose. Not less than 30,000 tons of farina were annually employed in *Europe for food purposes, of which his* company made 7000 tons. [illegible] and Italy. Glucose improved an inferior vintage. If the season had been deficient in sunshine the addition of glucose gave the wine the necessary alcoholic strength. In Bavaria, Wurtemberg, and Baden the use of malt substitutes was prohibited by law. The Farmers' League had a very strong hold on the Parliaments and had [illegible] however, was largely used. It was used in quantities of about three or four pounds of dissolved sulphur to the acre of hops, the object of its use being to prevent mould. In the early days it was used very *carelessly,* but not so nowadays when the greatest care was *observed.* Of course, in the case of a crop being threatened with ruin the grower would use sulphur very vigorously in order to save the crop and would do so even when it was in flower. The brewers, however, objected to the flower being coloured with sulphur. Having described the processes of drying and curing, witness said that he had known *hundreds of samples* of hops to be tested without a *trace of arsenic* being found in one of them. If arsenic were in any case found in hops then he should say that it must be due to the use of inferior fuel.

The Commission then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Brown.—On the 13th of May, at 6, Gibson-square, N., the wife of George Brown, M.R.C.S. Eng., of a daughter.

Fitzgerald.—On May 11th, at Southwood lane, Highgate, N., the wife of Gerald Fitzgerald, M.B., of a daughter.

Hentsch.—On May 12th, at Acre-lane, S.W., the wife of G. F. Hentsch, L.R.C.P. Lond., M.R.C.S., of a daughter.

Lansdale.—On May 9th, at Trinity square, S.E., the wife of Wm. Lansdale, M.D., M.R.C.S., L.R.C.P. Lond., D.P.H., of a son.

MacLeod.—On May 9th, at Ladbroke-grove, W., the wife of C. R. Alex MacLeod, F.R.C.S., of a son.

Plummer.—On May 11th, at Old Elvet, Durham, the wife of Selby Plummer, M.D., of a daughter.

Taylor.—On May 9th, at Eland House, Rósslyn Hill, Hampstead, Huldah, the wife of E. Claude Taylor, M.D., M.S., of a son.

Wace.—On May 11th, at Southgate-street, Winchester, the wife of Cyril Wace, F.R.C.S., of a daughter.

MARRIAGE.

Preston—Bowkett.—On May 8th, at Emmanuel Church, West Hampstead, Francis Harrison Preston, M.A. Camb., M.R.C.S., son of the late Rev. A. M. Preston, of Winslow, Bucks, to Hilda Emily, daughter of the late Dr. Bowkett of Poplar.

DEATHS.

Bayes.—Frederick William Bayes, M.R.C.S., of Walsingham, in his 76th year.

Braddon.—On May 10th, at the Imperial Hotel, Blackpool, Charles Hitchman Braddon, M.D., J.P., of Ryecroft House, Cheetham Hill, Manchester, and eldest son of the late Charles Braddon, surgeon, of Upton-on-Severn, Worcestershire, in his 64th year.

Davidson.—On Thursday, May 2nd, at The Dingle, Sydenham Hill, London, S.E., Lieutenant-Colonel D. C. Davidson, Indian Medical Service, Bombay Presidency, aged 60, youngest son of the late Rev. George Moir Davidson, of Watten, Caithness-shire, N.B., and son in law of the late General John Clarke, 25th Bengal N.I., and Commissioner, Sitapur, Oudh.

Holt.—On the 10th inst., at Hartshill, Stoke-on-Trent, Mary Ethel, wife of Arthur Knight Holt, M.D., of Bournemouth, and eldest daughter of Joseph Knight, of Newcastle-under-Lyme, aged 38.

Leigh-Sodipe.—At Lagos, West Africa, on the 15th April, 1901, Sodeinde Alfred Leigh-Sodipe, M.D., Assistant Colonial Surgeon, Colony of Lagos.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE SCOPE OF THE MIDWIFE'S DUTIES: AN INQUEST.

On May 9th Mr. A. Braxton Hicks held an inquest at Lambeth on the body of George Ernest Eyre, the five-days old son of a printer's labourer, living at 24, Caffin-street, Lambeth.—Elizabeth Lloyd, of 16, Caffin-street, said that she attended the mother of the deceased in her confinement, a midwife being also present. The baby was not a strong child when born.—Marian Langley, a midwife attached to Guy's Hospital Maternity Charity, residing at 10, St. Thomas's-street, S.E. (the Institution), deposed that she attended Mrs. Eyre in her confinement. The child was expected about that time. Witness was sent for on Sunday, May 5th, and went back again. The baby was born before she got there the second time. Mrs. Lloyd said it was a natural presentation. Witness attended to the mother and child. The latter was a little discoloured but quite normal. On the Monday afternoon, about 2 o'clock, witness again visited and she paid a further visit on Tuesday or Wednesday, when the child was apparently all right; she saw nothing the matter with it. It was not a large child. One of her assistants then took over the case—one of her pupils. She was there first and sent for witness.—The Coroner (surprised): You have pupils, do you? Where is it going to stop Pupils will be having pupils too, I suppose. I am not surprised at what the medical journals say about this midwife business. Although you are a certificated midwife, when a call is made you send a pupil, who finds something wrong and then you go. Do not you think you should have called the obstetric physician—a qualified practitioner?—Witness: I often have cases like this.—The Coroner: And I have often to hold inquests because a medical man, who could give a certificate, is not called and midwives take too much upon their own shoulders.—Witness went on to say that the nurse told her of the death at nine o'clock on Friday morning and she asked Dr. Sime, the physician, to see the child.—The Coroner: You did not see it?—Witness: No, sir.—The Coroner: You could not tell what was the cause of death, then why did you give this certificate:—

"Guy's Hospital.

"Guy's Institution, 10, St. Thomas's-street.

"This is to certify Mrs. Eyre of 24, Caffin-street, was delivered of a male child, April 29th, that it died May 2nd from inanition with convulsions. "Marian Langley, midwife."

Witness: I had seen the child.—The Coroner: The doctor could not give a certificate because he only saw the child after death. First of all this certificate is incorrect as to the date of death. It is on paper headed "Guy's Hospital," which gives it an official aspect. Why did you put "convulsions" when you never saw the child in one?—Witness: Dr. Sime saw the child and was of that opinion.—The Coroner: If Dr. Sime could not give a certificate, why should you? Have you ever had a case like this before?—Witness: No.—The Coroner: Then I trust you won't give another certificate. I never accept them because you are not qualified to give a certificate of any sort. If you believe what other people tell you you would have to believe anything Did Dr. Sime authorise you to give this certificate?—Witness: Yes.—The Coroner: Do you know of the new Bill for the Registration of Midwives?—Witness: I have heard of it.—The Coroner: That is one of the things it prohibits—the giving of a certificate of any description. In future always refer a case to my officer at once, because the registrar sends it to me. In this instance the alleged cause of death is not put down at all, because the registrar found it was a midwife's certificate. You have made a very fair guess, but it is not correct in one way.—Dr. Francis Wheeler Sime deposed to having made a post-mortem examination of the body by the coroner's order. There was an absence of any definite cause of death, but from his inspection of the body after death and the post-mortem examination he came to the conclusion that death was due to infantile convulsions.—The Coroner: Your midwife tells us that you said she might give a certificate?—Witness: Yes; of course, you see, we are not used to Lambeth. We have about 400 births a month and it is impossible for me to see them all.—The Coroner: If a child gets a convulsion and dies do you not refer it to the coroner?—Witness: If the registrar is not satisfied, we do, or, rather, we send the paper to the registrar, and if he is not satisfied he sends to the coroner.—The Coroner: The registrar knows less about it than anyone else and he might accept it and it would be an uncertified death. I do not think medical men should put so much power into the hands of registrars, some of whom do not know their work. I have no control over Southwark, but I used to have as deputy coroner. Anyhow, as far as Lambeth is concerned when you have a case in my district will you at once inform my officer who will make inquiries? Probably your opinion will be quite as valuable as if I had a post mortem made. This certificate I consider most irregular. The matter is of importance to the public at large, whom I represent to some extent.—The jury fully endorsed the coroner's observations.—The Coroner (to Miss Langley): I hope you will tell all your probationers not to take too much upon themselves.

MEDICAL MEN AND THE INCOME-TAX.

To the Editors of THE LANCET.

SIRS,—The very pertinent remarks in THE LANCET of May 4th, p. 1286, about medical men and the income-tax induces me to call the attention of others to what seems a great injustice. For instance, in returning the income from all sources in Schedule D, one naturally includes appointments. Well, the surveyor of taxes expects a return in Schedule E for the latter. I will explain. In the union with which I have been long connected—for the last 10 years—all the medical men are taxed separately on their salary, vaccinations, &c., which has become quite a burden. I have asked some of my neighbours to join me in agitating about this matter, but they seem diffident. Kindly advise what is the best thing to do.

I am, Sirs, yours faithfully,

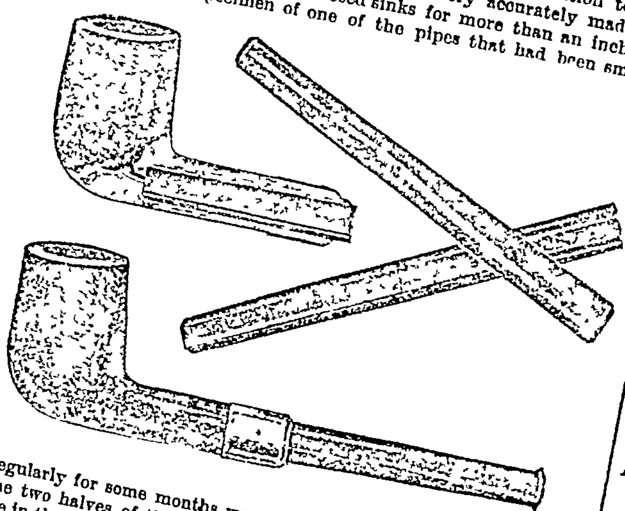
R. I.

May 13th, 1901.

*** We are not quite sure what our correspondent intends to convey to us, but if he means that he pays income-tax under both Schedule D and Schedule E on the same income he is obviously paying incorrectly. He should see the surveyor for his district, who will put matters straight for him.—ED L.

A NEW PIPE.

WE have had submitted to us specimens of a new pipe which, we consider, merits a few words of commendation. The novel feature is the vulcanite mouthpiece. This is split longitudinally so that the bore is represented in each half of the mouthpiece by a shallow trough. The two halves revolve on each other round a pin situated near the lip end, and are kept in close approximation to each other by the fact that the parts are very accurately made and that the whole tube when closed sinks for more than an inch into the bowl. A specimen of one of the pipes that had been smoked regularly for some months was submitted to us for inspection and the two halves of the mouthpiece were as perfectly joined as they are in the new pipes. The value of the innovation is obvious. When the pipe wants cleaning it is not necessary to use the accustomed form of pipe-cleaner. The mouthpiece can be opened and wiped and the pipe can be always kept dry. Smokers have brought to their notice a good many new ideas in pipes and are generally sceptical concerning the benefit to be derived from them, but the mouthpiece which we have described will, we think, repay their attention. The pipes are well-made and neat-looking. They can be purchased at the "M.P." Pipe, Limited, 79, Gracechurch-street, London, E.C., price 2*s.* 6*d.*



THE CASE OF MR. LOUIS FERDINAND DODS: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I have this morning received from Mr. W. J. Walsham a further list of contributions as under.

I am, Sirs, yours faithfully,

JOSEPH E. S. KING.

THE MAY-OATWAY AUTOMATIC FIRE DETECTOR AND POSITION INDICATOR.

ON Thursday, May 9th, at 23, Old Broad-street, London, E.C., there was a press view of a heat and cold detector which should prove valuable for both private and public use, if in actual practice it answers to the delicate tests which it responded to when shown to us. The principle on which the invention is constructed is that of the expansion or contraction of metals by change of temperature. A protected wire is suspended along one side of a room and from the wire falls a small plug which drops between two terminals and closes a circuit with an electric bell when the wire expands. By various simple mechanical and electrical appliances the information gained by the automatic detectors is systematically codified and announced either to the householder or the fire-station, or to both. As the course taken by the fire is indicated useless deluging of rooms from which only smoke is issuing is prevented. The apparatus can be adapted equally well to the recording of low temperatures and its use in cold stores and freezing chambers is thus indicated. When it is possible to summon trained aid this instrument is connected with the ordinary street alarm wires, in which case the signal reaches the brigade over its own wires by automatic telegraphy at the same time that the alarm is given at the seat of the fire. No human initiative is required, the premises may be quite unoccupied at the time, but within a few seconds the firemen will be apprised of the outbreak, and on their arrival will be shown its position and extent. According to a printed statement which we have received, "the May-Oatway system originated in New Zealand and is the joint invention of Mr. Chas. E. May, senior mechanical electrician to the Government of that colony, and Mr. G. H. Oatway. There the system is in general use, delivering its signals over the ordinary municipal streets alarm wires direct to the offices of the different brigades. Every fire insurance office (English, foreign, and Australasian) and every fire brigade testified in writing to its value; the Government of the colony have ordered its installation for the protection of the hundreds of inmates of the Industrial School; and the State Railways Department have opened negotiations for the right to manufacture and to use the invention under royalty to the Inventors' Syndicate. In England the system has secured the coöperation of Sir Eyre M. Shaw and Sir W. H. Preece, the two representatives of Great Britain at the International Fire Brigades Congress held in connexion with the Paris Exhibition last year."

BENZ MOTOR-CARS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers who have used the above cars in their practices say if they are to be relied on for a practice in a hilly country where gradients are steep, surface of main roads good, but of by-roads bad? Also cost of working and if, with ordinary care, they require frequent repairs.

I am, Sirs, yours faithfully,

CORNWALL.

May 14th, 1901.

"SEBORRHŒA."

To the Editors of THE LANCET.

SIRS,—Will "S.," whose communication appeared in THE LANCET of May 11th, p. 1378, try "Fowler's solution" internally? I have known scurf vanish like mist before a hot sun through it. Should he be inclined to try it, may I ask from him through your columns a note on the result? I was myself a martyr to the condition and Fowler's solution had good effect.

I am, Sirs, yours faithfully,

H.

May 13th, 1901.

◆

Miles Medicus.—The communication is too long for our columns. The story is told with obvious animus against the employer and would not if it were published create any prejudice in favour of the writer. At the same time the employer is acting unfairly in not replying to questions asked by other practitioners concerning his late assistant.

An Author who has been a Reviewer once, J. W., and *A. E.* are thanked for their communications, but if we opened our columns to lists of recommended fiction we should have difficulty in stemming the tide of suggestions which would reach us.

An Actor details a story which we can hardly credit. If he will send us copies of his letters to medical men and of their replies refusing to attend him we will do our best to assist him. He has not told us enough to make it safe to advise him.

Mr. F. Hallas.—A bottle containing a few drops of fluid—quite an insufficient quantity for analytical purposes—has been received.

P. J. T.—We do not give medical advice.

Jelloid.—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Blairgowrie Advertiser, Stratford Express, Carlisle Journal, Birmingham Post, Newcastle Journal, Southport Visitor, Bolton Chronicle, Shields Gazette, Surrey Times, Cheshire County News, Sheffield Daily Telegraph, Glasgow Herald, Chesterfield Times, Dundee Advertiser, Liverpool Daily Post, Halifax Courier, Crewe Chronicle, Bradford Observer, East Anglian Times, Hexham Herald, Manchester Guardian, Darlington Star, Scotsman, Citizen, Architect, Times of India, Pioneer Mail, Builder, St. Austell Star, Leeds Mercury, Edinburgh Evening News, Yorkshire Post, Reading Mercury, Bristol Mercury, Town and Country Journal (Sydney), Sydney Daily Telegraph, Middlesborough Morning Mail, Optician, City Press, Daily Colonist, Mining Journal, Surrey Advertiser, Lancashire Daily Post, Hertfordshire Mercury, Lancaster Observer, Le Courrier de la Presse (Paris), Blackpool Herald, Local Government Journal, Selkirk Reporter, The Age (Melbourne), St. Mary Cray Times, North Herts Journal, Kettering Guardian, Nuneaton Observer, Hunts County News, &c., &c.*

OPERATIONS.

[illegible]

2.30 P.M).

WEDNESDAY (22nd) —St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic [illegible]

London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (23rd) —St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M), Charing-cross (3 P.M.). St. [illegible]

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (20th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover square, W.).—7 P.M. Council. 8 P.M. Papers:—Mr. D. Caush: The Development of Pulp Nodules (with lantern illustrations).—Mr G. Brunton: A Method of Avoiding Pain in Dental Operations (incorporating an article by Mr. W. St. George Elliott). Casual Communication:—Mr. W. B. Barrett: A Case of Underhung Bite.

MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish square, W.).—8 30 P.M. Annual Conversazione Reception by the President. 8 45 P.M. Oration:—Mr. F. R. Cross: Some Landmarks in the Progress of Medical Science.

TUESDAY (21st).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.) —8.30 P.M. Annual General Meeting Election of Officers and Council. Communications [illegible] of the Pericardium. Card Specimens will be shown by Mr. T. Bryant, Dr. Fawcett, and Dr. Thursfield.

WEDNESDAY (22nd).—SOCIETY OF ARTS —8 P.M. Mr R. Brudenell Carter: Testing and Training Distant Vision, with special reference to Military Requirements.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.) —4 30 P.M. Informal Exhibition of Cases. 5 P.M. Annual General Meeting.

THURSDAY (23rd).—MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos-street, Cavendish square, W.) —11 A.M. Educational Committee. 12 noon. Parliamentary Committee. 1.15 P.M. Council Meeting. 2 P.M. Dr. Tredgold and Dr. Watson: Exhibition of Microscopic Slides. 3 P.M. General Meeting. Papers:—Dr. C. Mercier: Punishment.—Dr. R. P. Smith: A Case of Epileptic Homicide.—Dr. D. G. Thomson: Senile Insanity, in what Institutions should it be treated? 6.30 P.M. Dinner at the Café Royale, Regent-street.

FRIDAY (24th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 30 P.M. Annual General Meeting Election of officers for the session 1901-1902 Papers:—Dr. Risien Russell and Mr. Raymond Johnson: Traumatic Subdural Hæmorrhage on the Sixth Day after the Injury and Successfully Treated by Operation.—Dr. Isambard Owen and Dr. W. J. Fenton: Extreme Dilatation of the Left Auricle, the Auricle Presenting in the Right Axilla —Mr. Rickman Godlee Acute Suppuration of the Thyroid Gland complicating Typhoid Fever.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

MONDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.) —4 P.M. Mr. M Morris: Consultation. (Skin.)

WEST LONDON POST GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Bidwell The Application of Plaster-of Paris Splints

TUESDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.) —4 P.M. Dr. R. L. Bowles: Consultation. (Medical)

WEDNESDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C).—4 P.M. Mr. R. Harrison: Consultation. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST [illegible] Bruce: On the Diagnosis, [illegible]ent Tuberculosis (opening [illegible] COLLEGE AND POLYCLINIC [illegible] Hutchinson: Consultation. (Surgical.)

CHARING-CROSS HOSPITAL.—4 P M. Dr. Abercrombie: Medical Cases. (Post Graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Ball Methods of Examination of the Throat, Nose, and Ear.

FRIDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C.).—4 P.M. Dr. D. Grant: Consultation. (Ear.)

ASSOCIATION OF ASYLUM WORKERS (Medical Society's House, 11, Chandos-street, Cavendish-square, W.).—4 P.M. Annual Meeting.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not onl affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address
ON
THE OPERATIVE TREATMENT OF ABSCESS WHEN SITUATED IN THE BRAIN.

Delivered at a Special Meeting of the Otological Society of the United Kingdom held in Edinburgh on May 11th, 1901,

By CHARLES A. BALLANCE, M S. Lond, F R C S Eng,

SURGEON TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, AND TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET, SENIOR ASSISTANT SURGEON TO ST THOMAS S HOSPITAL.

Mr President and Gentlemen,—None of us can have forgotten the beautiful story of "Rab and His Friends"[1] wherein is painted by a master hand an operation by your great surgeon, Syme, in the pre-chloroform and pre antiseptic days The heartrending description of the operation would be true to this day but for the genius of Simpson, as chloroform—"one of God's best gifts to His suffering children"—might still be unknown. And the "Reaper whose name is Death"[2] would still be reaping the "bearded grain" by means of the bacillary "sickle keen"—the dread and fatal septic illness that cut off the life of Ailie—had not Lister, the peerless knight of surgery, after long years of toil, vanquished the terror of the surgeon Truly—

"[illegible]
[illegible]
[illegible]"

Indeed, we may detach some words from a sublime passage in which Macaulay immortalises the genius of an illustrious statesman and say of Lister "History will deliberately pronounce that among eminent men no one has left a more stainless and none a more splendid name"[4]

In the city where these greatest benefactors of humanity lived and taught it is indeed a high honour to have been called upon to open a scientific discussion. I did not know until I received the agenda paper that the subject intrusted to me was to occupy the whole time of the meeting. On looking over my paper on the journey north I could not help being struck with the contrast between even a practical paper and the triumphant achievements of the Edinburgh school The exclamation of Tony Lumpkin when Diggory handed him a letter came to my mind:—

"A damned cramp piece of penmanship as ever I saw in my life."[5]

The greatest trust between man and man, writes Lord Bacon in his essay on Counsel, is the trust of giving counsel We have it on the authority of his greater contemporary that

"Some men have greatness thrust upon them."[6]

This is my fate, for to offer counsel on the subject of the treatment of abscess of the brain presents transcendant difficulty, and to be requested so to do implies a trust in my ability which I am only too conscious will fall short of the standard set before me. In fact, not to put too fine a point upon it, I somewhat fear my fate may be comparable to that of Metis[7] whose name, Bacon tells us, signifies counsel It was her fate to be married to Jupiter who, as soon as she conceived, ate her up lest he might be deprived of any of her counsel I do not imagine that the members present will appraise my counsel so highly that they will be anxious to follow the lead of Jupiter, but should that consummation happen it is my fervent prayer that they may partake of a spiritual rather than of a corporeal feast Macbeth tells us—

"The time has been
That when the brains were out the man would die
And there an end."[8]

Though this dire calamity frequently dogs our footsteps, yet the times have changed, for now the society's "great consult begins,"[9] not, as in Milton's Stygian Council, held at Pandemonium, by the passing of "resolutions in despair,"[10] but having gained "reinforcement of hope",[11] from past success we—

" meanwhile revive,
Abandon fear, to strength and counsel joined
Think nothing hard, much less to be despaired."[12]

"Things unattempted yet" the advance of knowledge will make possible, the tide of Truth is ever flowing,

"For while the tired waves, vainly breaking,
Seem here no painful inch to gain,
Far back, thro' creeks and inlets making,
Comes silent, flooding in, the main."[13]

So it has been in the advance of surgery. Only by slow degrees has problem after problem been grappled with and solved One of the latest triumphs of the art of the chirurgeon is shown in the operative treatment of abscess of the brain In a steadily increasing number of instances it can truly be said of the surgeon —

" strangely visited people
All swoln and ulcerous, pitiful [in the brains],
The mere despair of surgery, he cures."[14]

Although in the surgical treatment of disease of the brain we are as yet only on the threshold of success, nevertheless the near approach of a perfect understanding of these matters may be confidently predicted Then will it be possible to enter into the thought of the Roman poet —

"No pleasure is comparable to the standing upon the vantage ground of truth [a hill not to be commanded and where the air is always clear and serene] and to see the errors, and wanderings, and mists, and tempests in the vale below"[15]

"The more I think of it," says Ruskin, "I find this conclusion more impressed upon me—that the greatest thing a human soul ever does in this world is to *see* something and tell what it *saw* in a *plain* way" In this paper an attempt is made to tell in a *plain* way a few of the things which I see with regard to abscess of the brain "Whether these seeings are there at all is another matter" The object in view is to induce my colleagues and fellow workers to tell also what they have seen "The practical bearings of our theme" are of incalculable interest to science and to man. Correct observation is the vital "thread which binds the facts" and widens the field of knowledge

General Considerations.

Before describing the exact details which must be carried out in th[illegible] the brain certain general [illegible] An abscess of the brain is [illegible] texture"[16] This tissue, [illegible] n the blood and inclosed in an inextensile bony capsule, is subject to the laws of hydrostatics The integrity of certain parts of it is essential to the continuance of life Placed within the cranium the abscess is, until exposed by operation, quite [illegible]

[illegible]

the objective and subjective symptoms upon which the diagnosis is made point to a lesion of the cerebral substance but do not indicate clearly its nature and extent The surgeon has to operate without any certain knowledge as to the size of the abscess and the acuteness of the inflammation, nor can he often truly surmise whether he has to deal with circumscribed or diffuse suppuration or both. Even when the history seems to point clearly to an acute condition it may be found that the abscess is of old standing. Abscess in the brain may be latent, producing only general symptoms of ill health, until excited to renewed activity by a febrile attack by a blow on the head or by some minor operation, such as the removal of a polypus. By a latent brain abscess, then, is meant one producing no symptoms directly referable to a lesion of the brain. Such an abscess is, in all parts of the body, inclosed in a capsule. An abscess producing slight symptoms over a considerable period of time may not be encapsuled. This is true of the brain as of the neck or any other region. This variety of abscess has a tendency to extend, causing local destruction of tissue. A history of long-continued cerebral symptoms does not necessarily point to the presence of a capsule around the area of suppuration, for in a case of cerebellar abscess with symptoms dating back at least eight months no capsule was found, but the whole cerebellar hemisphere was nothing but a shell of softened grey matter.[18] The two conditions of acute abscess and old encapsuled abscess may exist together, as in a case that occurred to one of my colleagues, now deceased, in which an acute cerebellar abscess was opened with relief to the symptoms, but at the necropsy an old encapsuled abscess was found internal to that which had been opened.[19] I have elsewhere drawn attention to several such instances.

The question must now be asked, How is an abscess of the brain to be treated? There can be no discussion as to the nature of the reply. Stäcke[20] says: "Otology is an offshoot of surgery and only in close adherence to it and in the true and conscientious observance of its principles is success to be sought for and to be found. The most important principle is the care for free unhindered spontaneous drainage." These significant words were written in reference to the treatment of middle-ear suppuration and they apply with equal force to the treatment of abscess of the brain, which is the only too frequent result of failure to comply with them. Success can only be won by close attention to those fundamental surgical principles which guide us in the treatment of abscess elsewhere. In one of the most recent text-books on surgery[21] we find these principles thus tersely stated: "In the treatment of an abscess there is one absolute rule which knows no exception—viz., that whenever and wherever pus is found the abscess should be evacuated at once, and after evacuating it thorough drainage must be provided for." To which may be added that when a purulent collection is encapsuled enucleation is the proper treatment. In the great majority of abscesses in the brain, as elsewhere, there is no capsule. The following is, however, an instance in which a capsule one-eighth of an inch thick was present, but owing to a mistake in diagnosis the abscess was not removed.

A man, aged 40 years, was admitted to hospital on Sept. 14th, 1895, with severe occipital pain, vomiting, and slow cerebration. He had paralysis of the right sixth nerve and double optic neuritis. He lay on his right side in bed. There were forced movements to the right and rotation to the right in walking. With the eyes shut he fell backwards and to the right. In the beginning of May in the same year he had a severe illness with shivering, sweating, and rigor, said to have been of influenzal origin. This had been followed by slight loss of power on the left side from which he had recovered. About 10 days before admission the headache and other symptoms returned. On the day following admission (Sept. 15th) a rigor occurred at 5.30 P.M.; at 6.30 coma was complete; at 7.30 artificial respiration was necessary and was continued until I arrived. I was told that the case was thought by the physician to be one of cerebellar tumour. Considering it almost impracticable to remove a cerebellar tumour during the performance of artificial respiration, and thinking that the left-sided paresis might be due to involvement of the right cerebral hemisphere, I removed a large area of bone over the right motor cortex. The brain bulged under great pressure, but natural respiration did not return. A trocar and cannula were plunged in up to the hilt and impinged upon a hard mass into which it would not penetrate. As this was thought to be a solid basal tumour which could not be removed the operation was abandoned. The necropsy revealed an encapsuled abscess containing an ounce of thick greenish pus, replacing the right optic thalamus. The capsule was very firm and quite one-eighth of an inch thick. This abscess might have been enucleated had it been recognised.

When there is no capsule the treatment is free incision and drainage, but the provision of drainage is more difficult in the brain than in other more solid tissues where, by free incision and counter-opening, it is easy to establish drainage and effect a cure. The difficulty is that in the "liquid texture" of the brain as soon as the abscess is opened the intracranial pressure causes the fluid brain substance surrounding the abscess to flow towards the surface, so that a large portion of the cavity of an unencapsuled abscess is at once shut off from communication with the incision.

Since micro-organisms behave in the brain as they do elsewhere in the body the question naturally arises, should the bacteriology of the abscess modify the treatment? It has been already pointed out that until the brain has been entered it cannot be discovered whether the abscess is localised or is spreading. The virulence of manifest suppuration presents clinical features which indicate its bacteriology to the mind of the surgeon who has had some training in that subject. These clinical signs cannot be observed in the case of brain abscess, but it is nevertheless supremely important to determine the nature of the micro-organism at the earliest possible moment, as the use of a suitable antitoxin may prove to be a valuable weapon in the fight against death.

DETAILS OF OPERATION.

We now proceed to consider step by step how the surgical principles of the treatment of abscess are to be carried out in the case of the brain. It is taken for granted that the local source of infection has been thoroughly removed. The abscess must now be exposed by an appropriate operation the steps of which are the following.

1. *Sterilisation of the skin.*—Shave the scalp, scrub it with ethereal soap and sterilised water, wash the soap away with sterilised water, rub firmly with turpentine on a sterile swab and then again with ether. If the operation is not to be done immediately apply sterilised lint soaked in a glycerine solution of perchloride of mercury (1 in 1000). If the operation is proceeded with at once swab the skin with strong carbolic or perchloride lotion.

2. *Anæsthesia.*—The anæsthetic should be chloroform and it should be given warily, for, especially in cases of cerebellar abscess, respiration is apt to cease. On two occasions it has happened in my experience that with the first few inhalations of chloroform respiration ceased and the operation had to be completed during the performance of artificial respiration. Neither morphia nor strychnia should be administered before the dura has been opened.

3. *Incision of the scalp.*—A flap is to be preferred to a crucial incision. It should be cut with its base downwards and should be considerably larger than the opening designed to be made in the skull.

4. *Opening in the bone.*—I am convinced that failure may result from neglect of the rule of surgery to make a free opening. How can a free opening into the abscess be effected through an inadequate opening in the bone?

> "Wounds by wider wounds are healed,
> And poisons by themselves expelled."[22]

The trephine employed should be five-eighths of an inch in diameter, of slightly conical shape, and should have the teeth outside. (*a*) In temporo-sphenoidal abscess the site of application should be about seven-eighths of an inch above the supra-meatal spine, the object being to expose the lowest part of the middle fossa just external to the tegmen antri and tegmen tympani. Immediately above these tegmina are the tissues in which, as a rule, the infective process first develops. When the disc of bone has been removed by the trephine more bone should be cut away with small saws, forceps, or Cryer's drill until the opening in the skull is enlarged to a parallelogram measuring one and three-quarter inches antero-posteriorly and one inch vertically. The lower edge of the parallelogram is marked by that of the trephine opening. Three-quarters of an inch of its antero-posterior extent should lie behind the centre of this aperture and one inch in front. The lowest part of any abscess in the temporo-sphenoidal lobe can be efficiently drained through this opening, and the bone disease which is the source of infection can be directly observed and removed. I have known a case where a temporo-sphenoidal abscess was opened at its highest part and where life was only saved by making a counter-opening in the situation here recommended, the man having been for some weeks in a condition of cerebral irritation. If the abscess is above and behind or above and in front of the opening more bone should be taken away, so as completely to expose the surface of brain which is external to it, or if the surgeon so prefer he can make a trephine opening higher up and utilise the lower aperture as a counter-opening. The former method is recommended. (*b*) In operating for cerebellar abscess the same trephine should be used. It should be placed on the bone so that its anterior edge touches the posterior border of the mastoid process. Its upper edge should be just below Reid's base line. In this way the horizontal and vertical portions of the sigmoid sinus are avoided. The opening should be enlarged backwards and downwards until it is quite one and a quarter inches in antero-posterior, and one inch in vertical, extent. The opening may require enlargement, especially in cases where the abscess extends into the posterior part of the lateral lobe. It cannot be carried forwards with much advantage as the vertical portion of the sinus is in the way of incision of the dura in this direction It is to be especially remembered that the removal of bone while comparatively easy before incision of the dura mater is not so satisfactorily accomplished when that membrane has been incised and the brain is bulging under pressure.

---

[22] Butler: Hudibras.

5 *Incision of the dura mater.*—Here, again, a flap is preferable to a crucial incision. A small aperture should be made with a knife and the flap (having its base upwards)[23] should then be cut with fine blunt-pointed scissors. Great care must be taken to avoid wounding the vessels of the cortex which are forced by the intracranial pressure into close contact with the membrane.

6. *Discovery and incision of the abscess.*—When there is a sufficient opening in the bone it may be possible to determine by palpation that the abscess is immediately sub-cortical. An incision should at once be made through the intervening portion of brain substance into the abscess cavity, care being taken to avoid wounding the vessels as in other parts of the body. The use of a trocar and cannula, a pus-seeker, or other special instrument is unnecessary and contrary to surgical principles. If the site of abscess is not obvious it must be sought for by exploratory puncture, and in so doing it should be remembered that the site of the abscess is almost certainly close to the bone disease which gave rise to it. The best instrument to use is a sharp-pointed, long, and narrow knife. Our brains are not like *Satan's*—

"Entrails, heart or head, liver or reins,"[24]

which Milton tells us could

"Not in their liquid texture mortal wound
Receive, no more than can the fluid air";

and a wound made by the surgeon's knife will not heal quite so readily as that inflicted by the sword of Michael; yet in the brain, as elsewhere, clean-cut wounds heal more readily than any others, and there is certainly less risk of the abscess being missed when search is made for it with a sharp knife than when any other instrument is employed. Cases could be related of (1) trocar and cannula missing the abscess; of (2) trocar and cannula passing through the abscess without tapping it; and of (3) trocar and cannula striking the abscess but failing to penetrate its capsule (as in one case already related). The following is an instance of trocar and cannula failing to evacuate a large abscess. The brain was explored in various directions with a trocar and cannula with a negative result. At the necropsy there was found a large abscess with very thick walls containing over four ounces of green offensive pus. So thick was the wall that the abscess shelled out whole and could be rolled about the table. In fact, it needed a sharp plunge with the knife to open it.[25] The use of the knife for the evacuation of an abscess of the brain is not a new operation, but was taught and practised more than a century ago. Dupuytren[26] in one of his lectures says: "In certain cases of deeply-seated fluid collections we must incise the dura mater, the arachnoid, the brain itself if the *focus* is at the surface of this organ, and by this bold proceeding patients have been saved." A little further on in the same lecture he continues: "Relying also on the success of J. L Petit, Boyer concurs in the advice of Quesnay and does not fear to plunge the bistoury quite deeply (*assez profondément*) into the very substance of the brain in order to evacuate traumatic effusions which may have formed there, and it has fallen to my lot to do so several times with success." Like many another step in the advance of knowledge this advice, though justified by some brilliant successes, remained for a considerable time a dead letter, for we find a great English surgeon writing nearly half a century later: "There are few surgeons who would have the hardihood of Dupuytren, who plunged a bistoury into the substance of the brain and thus luckily relieved the patient of an abscess in this situation."[27] And after yet another decade the famous case of Dupuytren is thus alluded to in a later edition of the same work: "This was doubtless a somewhat rash thing to do without previously ascertaining the presence of pus by milder means."[28] Dupuytren, in his account of this historical case, says simply: "I incised the dura mater, nothing came out; I thrust a bistoury cautiously" (? so as to avoid the vessels of the cortex) "into the brain and there welled up immediately a flood of pus. That very night all the symptoms disappeared and the patient recovered."[29] If careful exploratory puncture with the knife fail to find the abscess the finger inserted into the brain substance will almost infallibly detect the presence of a tense abnormal swelling. Mistakes, however, may still be made, as is illustrated by two cases related in my article on "Certain Affections of the Ear" in Clifford Allbutt's "System of Medicine." In one of these one cerebellar abscess and in the other two had been opened, yet both patients died from an unopened abscess, oyster-like in shape, lying immediately beneath the cortex of the upper surface of the cerebellar hemisphere. The examining finger felt the sensation of resistance, but this was attributed to the tentorium.

7. *The further treatment of the abscess.*—When the cavity is not entirely closed by the waves of brain substance it may be gently irrigated with a weak antiseptic; but on no account should this be done unless two drainage-tubes are so arranged as to insure the free escape of the fluid. Sterilised normal saline solution is recommended. Unless the opening in the cortex is large I am opposed to the tamponing or packing of the cavity with gauze because the tampon tends to obstruct the free exit of septic material. In one case of abscess of the temporo sphenoidal lobe in which I removed a large area of bone I ligatured and removed the cortex corresponding to the outer boundary of the abscess. The inner wall of the abscess which was at first treated by gauze plugging soon came to form part of the outer surface of the brain and was thus directly accessible for dressing. The best results ensued.

As to drainage-tubes, the rules for their use in abscess of the brain do not differ in any way from those which apply to their employment in the healing of suppurating areas elsewhere. When a tube has been successfully introduced it should not be disturbed for some time. The most successful cases treated in this way are those in which the tube remains undisturbed for many days. Tubes are shortened or removed only as the cavity heals from the bottom. The nature of the tube is of little consequence. All tubes are liable to become blocked with brain débris.

In the case of a small abscess deeply placed in the anterior and inner portion of the cerebellar hemisphere the surgeon may be unwilling to use the knife for evacuation. Recourse must then be had to the exploring trocar and cannula, the latter having rings of wire attached by which, when it has penetrated the abscess, it may be immediately fixed to the scalp by silkworm gut. Many a case has been lost after the pus has been evacuated owing to failure to re-introduce the tube in the proper position. The trocar and cannula should be of platinised silver. In the event of a counter-opening being made or of drainage occurring through the external auditory meatus gentle irrigation through the diseased area of brain is beneficial, just as it is in cases of abscess with a counter-opening elsewhere.

8. *Closure of the wound and dressing.*—An aperture is now made in the base of the flap of the size of the opening in the brain, and the edge of the flap is replaced in position and sutured with fine silkworm gut. A powder may be used for dusting around the wound but it should be sterilised. The dressing may be of sterilised cyanide gauze, either used dry or wrung out of carbolic lotion (1 in 40). A dry sterilised cyanide dressing is recommended and the bandage should, if possible, be so managed as not to cover the forehead.

9. *After-treatment.*—This is a matter demanding the close

---

[23] Suggested to me by Dr C. D Green.

[24] "Paradise Lost, Book VI, line 346.

[25] Abbott: St Thomas's Hospital Reports, vol. xxv, p. 205.

[26] Leçons Orales, second edition, vol vi., pp 183-4 (published 1839, date of lecture not given).

[27] Erichsen's Surgery, seventh edition, 1877, vol i., p. 532.

[28] Ibid., ninth edition, 1888, vol. i., p. 781.

[29] Leçons Orales, Ibid., p. 146.

personal attention of the operator. The dressing may require to be changed daily or not at all, according to the nature of the disease and the condition of the wound. (1) The primæ viæ should be kept open by the administration of some preparation of mercury. I have found, too, in septic cases that the pill of colocynth and hyoscyamus is very efficient in clearing the intestine of foul-smelling fæces. (2) In regard to food it may be noted that barley-water and beef tea are often borne by the stomach when milk is rejected. (3) As to alcohol, in certain cases we can hardly do without it. When it must be given I personally prefer to order old brandy, though in this city old Scotch whisky would, no doubt, be selected. Far be it from me to assent to the "startling question" of the gifted Calverley[30] that both the ancient Greeks and the Scotch ought to have invented and adhered to another beverage.

> "The Greek mind must have had some vital fault,
> That they should stick to liquors so injurious—
> (Wine, water, tempered p'raps with Attic salt)—
> And not at once invent that mild, luxurious,
> And artful beverage, Beer." ....
> Then nectar—was that beer, or whisky-toddy?
> Some say the Gaelic mixture, *I* the Saxon:
> I think a strict adherence to the latter
> Might make some Scots less pigheaded, and fatter."

(4) Hernia cerebri is an evidence of sepsis. It is best treated by sterilised antiseptic dressings. To prevent the dressing from adhering to the hernia some form of protective should be used—perhaps gold leaf is the best; slight elastic pressure is useful in the later stages of the treatment.

10. *Recurrence of symptoms.*—It is by no means uncommon to have a return of symptoms a few days after the evacuation of the abscess, due either to the refilling of the abscess cavity from faulty drainage or to the formation of a new abscess in another part of the same lobe. In the cerebellum it is by no means infrequent to have a second or even a third abscess. Instead of concentrating the attention on the original site of abscess the new symptoms, such as high temperature, rapid irregular pulse, screaming fits, retraction of head, general twitchings, vomiting, drowsiness, &c., may suggest conditions such as meningitis or acute distension of the ventricles which are not present. The surgeon being led astray by these speculations may fail to act wisely. We may perhaps apply the words of Goethe[31]:—

> "I tell you what; your speculative wretch
> Is like a beast upon a barren waste,
> Round ever round by an evil spirit chased,
> Whilst all about him fair green pastures stretch.

Your great countryman, Carlyle, has said: "Genius is the transcendent capacity for taking trouble first of all." And Joubert has written: "Genius begins great works, labour alone finishes them." Both of these maxims are eminently true of the treatment of abscess of the brain. In order to succeed the surgeon must "take trouble first of all" in weighing well every point in the history and symptoms of the case and in planning and executing the operation with minute attention to every detail. And in order to finish his "great work" he must spare neither labour nor time in watching the progress of the case and in personally carrying out all the minutiæ of the after-treatment. Many are the vicissitudes of the days and weeks that follow the operation. To be able to choose with certainty and to carry out with precision the various measures which make for success and oppose a disastrous termination the surgeon must have at his command an exact knowledge of the significance of the various symptoms that arise and of the resources and methods available for their systematic treatment. The surgeon cannot here delegate his duties or shift his responsibility, and amid the difficulties that beset him in combating the disease he may well utter the prayer which the veterans of Frederick the Great sang as they marched to meet the foe at the battle of Leuthen—

> "Grant that with zeal and skill this day I do
> What me to do behoves, what Thou command'st me to
> Grant that I do it sharp, at point of moment fit,
> And when I do it grant me good success in it."[32]

And when the case has been brought safely through all difficulties and dangers into the smooth water of convalescence we may well say of the surgeon who saves his patient as Bunyan[33] did of his victorious pilgrim:—

> "Hob-goblin nor foul fiend
> Can daunt his spirit;
> He knows he at the end
> Shall life inherit!
> Then fancies fly away,
> He'll fear not what men say;
> He'll labour night and day"
> [To save his patient].

In conclusion, allow me to say how well I know the toughness of the problem which the surgeon has to face in coming to a decision to operate in certain cases suspected of harbouring an abscess of the brain. The advice given to Richard Plantagenet is much to the point:—

> "But yet be wary in thy studious care."[34]

Delay as the result of consultation may be disastrous, "for occasion turneth a bald noddle after she hath presented her locks in front and no hold taken";[35] and "the ripeness or unripeness of the occasion must ever be well weighed."[36] On the one hand, boldness alone is "ill in counsel, good in execution"[37]; on the other hand, "it is a dangerous thing to trace the thread of knowledge a little way and fancy we have found the end."[38] What is required in consultation is knowledge, experience, a grave sense of responsibility, and the strength to accept the consequences arising therefrom; indeed, to fulfil the Pauline exhortation, "Be strong—quit yourselves like men."[39] When the decision to operate is made it should be acted upon at once; hesitation or delay may be fatal. A patient suffering from cerebellar abscess has died in the night, the operation having been arranged for the following day—"True despatch is a rich thing." "Yet and but,"[40] said the Templar in "The Talisman," "are words for fools; wise men neither hesitate nor retract, they resolve and they execute."[41]

But still, in spite of all our care and pains, success may be wooed in vain. There may be no abscess or, if present, it may not be found.

> "The best laid schemes o' mice an' men
> Gang aft agley,
> An' lea'e us nought but grief an' pain
> For promis'd joy."[42]

"The smallest actual good," says Macaulay, "is better than the most magnificent promises of impossibilities"; and the stay of the surgeon in the midst of depression, discouragement, and defeat is the consciousness that he has "faithfully rendered an unrewarded obedience to the command"[43] of the Preacher.[44]

> "The man who though his fights be all defeats
> Still fights
> Enters at last
> The heavenly Jerusalem's rejoicing streets"[45]
>
> "In earthly races
> To victors only do the heralds call;
> But, oh! in yonder high and heavenly places
> Success is nothing and the work is all."[46]

Yet, kindled by the past the surgeon may surely say, "I shall arrive ...... the succession cannot break. The further evolution must go on the Higher Kingdom come; first the blade where we are to-day; then the ear where we shall be to-morrow; then the full corn in the ear which awaits our children's children and which we live to hasten."[47]

HEALTH OF CHELTENHAM.—Dr. J. H. Garrett, medical officer of health of Cheltenham, has just issued his report on the sanitary condition of that borough for the year 1900, the statistics which he presents being on the whole the most favourable in the history of the borough. The zymotic, infant, and general death-rates were all below the average. The general death-rate of 14 per 1000 is a record, and in portions of the borough—namely, in the South and West Wards taken together—it was only 10·3 per 1000. The mortality from the chief zymotic diseases was 0·71 per 1000. The infant death rate was 115 per 1000 children born. The highest birth-rate during the last 10 years was 22·5 per 1000 in 1893; in 1900 it was 19·7 per 1000.

The Erasmus Wilson Lectures

ON

THE PATHOLOGY AND DISEASES OF THE THYROID GLAND.

Delivered at the Royal College of Surgeons of England on Feb. 18th, 20th, and 22nd, 1901,

By WALTER EDMUNDS, F.R.C.S. Eng.,

SURGEON TO THE TOTTENHAM HOSPITAL; SURGEON TO OUT-PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

LECTURE III.[1]

Delivered on Feb 22nd, 1901

Mr. President and Gentlemen,—With respect to myxœdema and cretinism, as time is short, it must suffice to say here that the working out of the nature and treatment of these diseases is one of the most brilliant of the recent advances of medicine, and that our knowledge of their pathology seems now so well established as to admit of little discussion and to justify us in treating it as firm ground from which to proceed to the investigation of other and probably more complex ailments. But there is one point in connexion with myxœdema which may detain us a minute as it has led to some diversity of opinion. We have seen that in experimental removal of the thyroid gland (whether the parathyroid glands are also removed or not) there is often a narrowing of the palpebral fissures; in myxœdema the palpebral fissures are also narrowed, but the narrowing is generally attributed to the swollen condition of the eyelids. It is, however, doubtful if this is the whole explanation, and, indeed, Allen Starr says distinctly that it is not. "In myxœdema," he writes, "there is a marked tendency to abnormal heaviness of the eyelids, so that the upper lid falls and the eyes are never widely open. This falling of the lid appears to be independent of its thickening by the myxœdema; there is also a retraction of the eyeball. I have noticed in all my cases after a cure of the myxœdema that the eyeball had been previously decidedly retracted, so that when the patient was cured and the eyeball was in its natural position the previous retraction, as shown by photographs, became noticeable."

With respect to cases of sporadic goitre without symptoms—that is to say, cases in which the presence of the goitre is the only trouble—it seems now to be clearly established that the administration of thyroid gland is the best treatment. I had under my care a case of ordinary goitre in a young girl which was treated with some success with iron, iodide of potassium, and other remedies, but it was not until thyroid gland was administered that rapid improvement took place. Some time after the cessation of treatment a little enlargement of the thyroid gland reappeared, but this again was speedily removed by thyroid gland treatment. A second case of goitre was also cured, at least for a time, by thyroid gland administration. The effects of this treatment are so good that it must be regarded as a specific remedy; if it is, the enlargement of the thyroid gland must, in part at least, be attributed to an attempt at compensation, and that attempt must be unsuccessful, for otherwise the increase in size would not proceed to the large dimensions that it does

Formerly goitres were occasionally treated by excision, but the constitutional results following this operation were often so serious that complete excision is now abandoned. These results were: (1) a feeling of weakness and lassitude; (2) coldness of the hands and feet even in summer; (3) slowness of thought, of speech, and of other movements; (4) œdema of the eyelids, lips, hands, and feet; (5) bulkiness of the face, hands, feet, and trunk; (6) dryness of the skin and the falling out of the hair; and (7) in children an arrest of bodily and mental development. These symptoms were almost always chronic in their character, and their resemblance to the effects of experimental excision of the thyroid gland proper is noteworthy; but one case of acute myxœdema is on record. From a girl, aged 18 years, the late Sir William Stokes excised one lobe of a large goitre; the only result was a satisfactory diminution of the remaining lobe. After three and a half months the remaining lobe was excised; this after 11 days was followed by convulsive seizures, puffiness of the eyelids, the face, the hands, and the feet. mental torpidity, and slowness of speech. The patient died from exhaustion only 21 days after the second operation. The absence of ill-effects after the first operation and the rapidly fatal termination after the second resembles what happens in dogs after the removal of the thyroid gland and the parathyroid glands first on one side and later on the other. Although in goitre the removal of the whole thyroid gland is now not practised the removal of one lobe is not unusual, both in ordinary goitre and in Graves's disease; this, as in Sir William Stokes's case, is often followed by shrinking of the opposite enlarged lobe. When a goitre causes dyspnœa by pressing on the trachea it becomes necessary to remove a portion, and generally the isthmus is excised; this operation, too, is often followed by atrophy of the enlarged lateral lobes. It is necessary to remember in connexion with pressure symptoms that attacks of dyspnœa occur in Graves's disease, and also, it is said, in ordinary goitre, quite apart from any mechanical cause; they are similar to, and presumably due to the same cause as, the attacks of rapid breathing which constitute so prominent a symptom in the experimental aparathyroidea of dogs.

It is probably best to include under the term "Graves's disease" all cases of goitre with symptoms not to be explained by pressure No dividing line can be drawn between the typical cases and those with less pronounced constitutional symptoms.

With respect to the pathology of Graves's disease it has been discussed whether the primary lesion is in the nervous system or in the thyroid gland, whether, in other words, some nervous derangement causes the goitre and other symptoms or whether the goitre is the cause of the exophthalmos and cardiac disturbance. Originally the starting point of the disease was thought to be the cervical sympathetic, but latterly it has been contended that the secretion from the goitre is the cause of the palpitation. the exophthalmos and the other symptoms. This view has been urged by Möbius in Germany and in this country by Professor Greenfield in the Bradshaw Lecture of 1893 There is much to be said in its favour. In the first place, in an ordinary case of Graves's disease the enlargement of the thyroid gland is, as a rule, obvious, and when the opportunity offers it may be seen under the microscope that the gland is in a state of active secretion. On the other hand, the nerve lesions are extremely uncertain: one observer has found one change, one another, and when in a fatal case of Graves's disease a systematic examination of the nervous system has been made the result has generally been negative. Secondly, the marked contrast that exists between myxœdema and Graves's disease supports the thyroid secretion view. The first, at least in this country, to emphasise these distinctions was Byrom Bramwell and they are well set forth in his recent work. 1. In myxœdema the thyroid gland is atrophied and its secreting structure is destroyed; in Graves's disease the thyroid gland is enlarged and its secreting structure, though modified in character, is increased in quantity. 2. The symptoms of myxœdema almost always come on slowly and insidiously; those of Graves's disease not infrequently come with considerable rapidity, sometimes, indeed, after profound emotion, suddenly 3 Myxœdema is usually developed at a later age than is Graves's disease; it comes, as a rule, between 35 and 45 years of age while Graves's disease appears between the ages of 15 and 35 years, very rarely after 50 years of age. 4. In myxœdema the temperature is subnormal; in Graves's disease it is usually normal, but temporary elevations occasionally occur, its equilibrium being easily disturbed, and the patients often complain of a feeling of heat and cold. 5 In myxœdema the skin is extremely dry and harsh and perspiration is diminished, in Graves's disease the skin is moist and perspiration is increased 6 In myxœdema the bowels are usually constipated whereas in Graves's disease diarrhœa is not uncommon 7 In myxœdema the mental condition is placid and slow, while in Graves's disease there is considerable mental excitement. 8 Myxœdema is much benefited by thyroid gland treatment; Graves's disease is not, as a rule, benefited by this treatment, and some cases are made worse by it. A third argument in favour of the thyroid secretion view is that, as we have already seen, most of the symptoms of Graves's disease other than the goitre can be produced by the administration of thyroid preparations. A fourth argument is found in the cases of ordinary goitre which after years become converted into cases of Graves's disease; it seems more probable that some change should have occurred in the thyroid gland or secondarily to it than that a primarily central nervous lesion should have produced no other symptoms for years. Graves's disease is not known to occur secondarily to myxœdema. A fifth argument is derived from the good effects which often follow the removal of a portion of the goitre in Graves's disease. In a considerable number of these cases the removal of a lobe of the enlarged thyroid gland has been followed by marked improvement and, indeed, by cure. But there are certain objections to the secretion view. There seems no doubt that the thyroid gland is always enlarged in Graves's disease and that it is in a state of active secretion, but it does not follow that its secretion is identical with that in health, and although the observations of Hutchison and Soupault tend to show that it is, too much stress must not be laid on arguments derived from the action of normal colloid. In the thyroid gland in Graves's disease there is proportionately less colloid and in some cases no colloid at all. The microscopical examination of the thyroid gland in Graves's disease reveals various changes: (1) the vesicles instead of being round or square in section become branched and stellate; (2) the lining membrane is folded on itself; (3) the secreting cells instead of being cubical are columnar; and (4) the colloid in the vesicles has partly or wholly disappeared and its place is taken by a secretion which takes the microscopic stains badly. Now these changes are practically identical with those of compensatory hypertrophy as seen in animals after partial removal experiments. Indeed, the resemblance is so close as to lead to the conclusion that the changes in the thyroid gland of Graves's disease are also compensatory in character—in other words, that they are secondary to some defect elsewhere in the system; that defect may possibly be in the parathyroid glands, but there is no evidence on that point either way at present. In my experiments of excising the parathyroid glands the thyroid lobes underwent these changes microscopically, but to the naked eye they did not seem enlarged; on the contrary, some of them appeared to be smaller (Figs. 12 to 20). It must be admitted that occasionally in cases of goitre without Graves's symptoms similar appearances are seen, but, as far as my experience goes, this is exceptional. Also against this view may be shown sections from two cases of adenoma of the thyroid gland; in one the sections are like normal thyroid gland and in the other there are hypertrophic changes. The first case had no constitutional symptoms; the second was a case of Graves's disease.

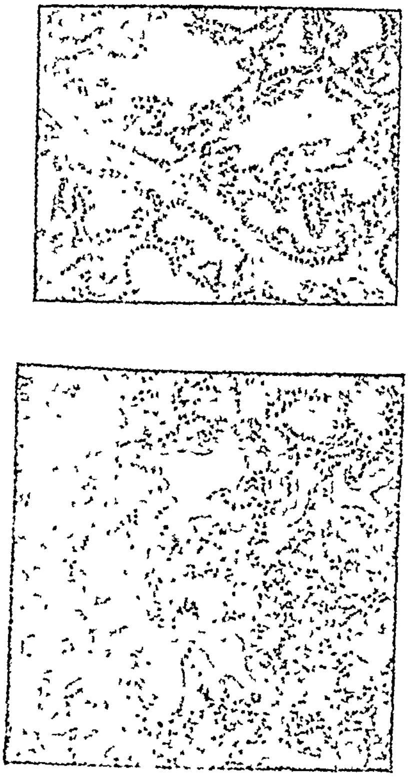
The treatment of Graves's disease has been carried out on various lines. The most obvious treatment is rest This no doubt benefits the disease, or at least reduces the symptoms, but it is doubtful how far the benefit persists after the patients are up and about again, and unless they are equal to resuming their natural occupations they cannot be said to be cured or even to be nearly cured. Change of air and quietude are also obviously indicated. With respect to the administration of medicines various drugs have been tried. Belladonna stands in good repute; it may be supposed to diminish the internal secretion, but its reputation is far older than our modern ideas about internal secretion. Bromide of potassium is also given to quiet the nervous system, valerian has been prescribed with the same idea. In order to reduce the size of the goitre iodine has been used both internally and externally. For their action on the heart digitalis and strophanthus have been given, also as tonics quinine and iron. The administration of thyroid gland preparations has been tried and has given different results in different cases; as a rule in doses which would benefit myxœdema no marked results have ensued. In some cases it has been attended with benefit, while on the other hand it has undoubtedly made some patients worse. This was clearly so in a case recorded by Auld in which the exophthalmos was increased, the pulse-rate was raised from 99 to 138, the temperature was elevated above the normal, and diarrhœa, sickness, and vomiting were brought on. Thymus gland feeding has been recommended, but it often fails to be of any use. Pregnancy, when it occurs, is stated by Charcot to be of marked benefit in Graves's disease; he mentions two cases and cites in support the high authority of Trousseau. But Graves's disease sometimes arises during pregnancy. Myxœdema is also said to be benefited by pregnancy, the explanation given being that the mother shares the advantage of the thyroid gland of the unborn infant. This view is supported by the abnormalities found in the thyroid gland of the puppies of partially thyroidless bitches. Halsted found in the puppies of a bitch from which one lobe of the thyroid gland had been removed and which had been sired by a dog that had also in part been deprived of its thyroid gland that the thyroid lobes in the puppies were 20 times larger than were those of normal puppies. I have repeated this experiment of Halsted. From a bitch there was removed on one side the whole of one lobe of the thyroid gland, including the parathyroid glands, and from the other side nearly the whole lobe, leaving, in fact, only one parathyroid gland and a morsel of

FIG. 13 AND FIG. 14.



The upper figure shows compensatory hypertrophy in the thyroid gland of a dog 41 days after partial excision of the gland. The lower figure shows the thyroid gland from a case of Graves's disease.

the thyroid gland proper. Notwithstanding this extensive removal of thyroid gland it lived and about four months after the operation it gave birth to a puppy I found in the puppy that the thyroid lobes were large (at least they appeared so to me) On microscopical examination it was found that there was an entire absence of colloid and that the secreting cells, instead of being cubical, were columnar; these are the changes of compensatory hypertrophy and are presumably due to an attempt to compensate for the absence of the thyroid gland in the mother

Graves's disease has been treated by operative methods. These are mainly three—namely, operations on the cervical sympathetic, operations for diminishing the blood-supply to the gland by ligaturing some of its supplying arteries, and operations for the removal of portions of the goitre The operations on the cervical sympathetic are based on the idea that these nerves are the starting point of the disease. We have already discussed the question as to how far the thyroid gland is, and how far the nervous system is, the primary seat of the disease; even if we decide in favour of the nervous system the question arises whether it is the sympathetic or the cerebro spinal system that is at fault. The fact that the internal secretion of the thyroid gland can be sufficiently arrested by division of its supplying nerves to cause death shows clearly that there must be a centre for it in the medulla; we must therefore conclude that even if the nervous system is the starting point the fault lies with the cerebro spinal system and not with the sympathetic. Still, even if the sympathetic is not the primary cause it may be materially involved in the evolution of the symptoms, and of this there is considerable evidence.

Of the five cardinal symptoms of Graves's disease it seems probable from the experiments related in the last lecture that the sympathetic has to do with the exophthalmos. The heart symptoms can be explained either by a continuous spasm of the accelerator nerves from the sympathetic or by a weakening of the action of the inhibitory fibres from the vagi The latter seems to be the much more probable condition, but there is no reason why the two conditions should not co-exist. Indeed, von Cyon says that in the goitrous animals of Berne they both are present. As to the goitre, the secretory fibres to the thyroid gland would seem to come, as far as we know, by the cerebro spinal and not the sympathetic nerves, and if so the sympathetic would have little to do with the enlargement of the thyroid gland. As to the blood vessels, the goitre, as may be seen in the post-mortem room, is a very substantial thing, not to be explained by engorgement of vessels; moreover, the vaso motor nerves in the sympathetic are constrictors and would make the thyroid gland, if anything, smaller and not larger. The tremors and mental excitement in Graves's disease would be connected with the cerebrospinal and not with the sympathetic system. Even if the sympathetic is the starting-point, it is necessary to consider whether any operation on it which would be likely to be beneficial is feasible In the dog the augmentor fibres of the sympathetic are derived from the inferior cervical sympathetic and the annulus of Vieussens. As in man the third ganglion is behind the subclavian artery and the annulus round it the operation for their removal would be extremely difficult, especially on the left side, for it must be remembered that the operation has to be done on both sides. It is true that in man there are from the superior and middle cervical ganglia cardiac branches which may be augmentor, but as in the dog the augmentor fibres come exclusively from the lower part of the cord it is probable that in man also they do so mainly However, sympathetic operations, varying no doubt in severity, have been performed in man and we proceed to see with what results.

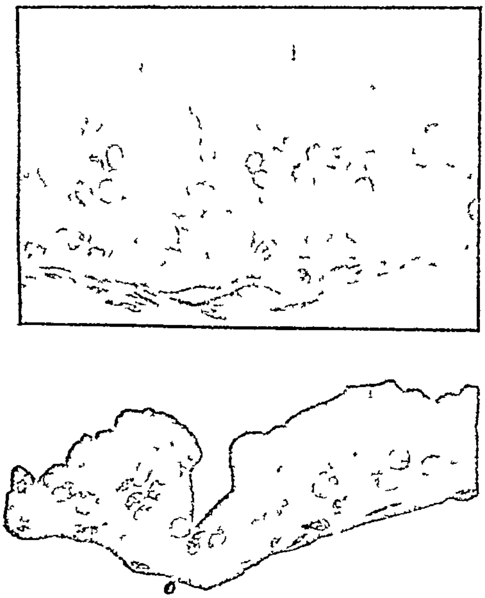
Boisson in a thesis for the M D. degree of Paris has collected all the cases he could obtain up to 1898, and to them he adds a valuable critical study of the whole subject. Altogether Boisson has collected 27 cases, but four of these he excludes from analysis as they, for one reason and another, prove nothing Of the remaining 23, 15 were well-marked cases of Graves's disease and eight were ill-defined or *fruste* cases Of the 15 well marked cases two were cured, six were much benefited, three were slightly improved, and one received no benefit, while there were three deaths. Of the eight ill defined cases one was cured, two were much improved, four were slightly benefited, and one was not benefited. By adding the two series together we get as a result of 23 cases operated on: three cured, eight much improved, seven slightly improved, two not improved, and three deaths. Boissou sums up thus: "Successes are rare; in cases benefited it is sometimes one symptom, sometimes another which is improved, and the improvement is sometimes immediate, sometimes late; sometimes there are relapses in the improvement. There are, too, cases of no improvement and cases of death. Neither by division nor by excision, total or partial, have more brilliant results been obtained. From the physiological point of view, too, all is chaos. There is no agreement, no relation between the phenomena noted by the surgeons and those observed by the physiologists; also the surgical effects are in disaccord one with another." Finally, Boissou concludes: "If surgeons have been able by this new operation to modify Basedow's disease the results obtained have no constancy and are as much confused therapeutically as physiologically."

Considering the gravity of those cases in which the exophthalmos leads to ulceration of the cornea I have especially analysed the 27 cases of sympathetic operation collected by Boissou with respect to the effect on the prominence of the eyes Of the 27 cases seven must be omitted either because there was no exophthalmos to start with or because from some cause the record is imperfect. There remain 20 cases; of these seven are said to have been cured of their exophthalmos, five were much benefited, seven derived little or no benefit from the operation as far as the exophthalmos was concerned, and in one subsequently to the operation both corneæ sloughed and the patient, who became blind, died from Graves's disease. This last case and the seven cases in which no improvement followed show that the sympathetic operation is not a specific even for the exophthalmos. Also this last case, in which the patient lost her eyesight and finally died from severe Graves's disease 10 weeks after the sympathetic operation on one side and seven weeks after its removal on the other side, shows clearly that the sympathetic is not the *fons et origo mali.*

FIG. 19 AND FIG. 20.



The upper figure shows the secreting cells in compensatory hypertrophy of the thyroid gland of a dog The lower figure shows the secreting cells from the thyroid gland in a case of Graves's disease

The subject of these sympathetic operations was dealt with by Mr J. Berry in a discussion on a case of Graves's disease at the Royal Medical and Chirurgical Society last year. He expressed the opinion that the sympathetic has nothing whatever to do with Graves's disease and that the sympathetic operation should never be performed. He referred to Boissou's monograph and opined that those who would read it would agree with him; that certainly has been the effect of its perusal on myself. There is, however, a small class of cases in which one might be tempted to perform a limited operation on the sympathetic; I refer to cases of ulceration of the cornea. As these only occur in patients in whom the eyelids cannot be closed the complication must be due mainly, if not wholly, to irritation. Since division of the sympathetic will reduce proptosis, this operation might be tried in these cases, although, as we have seen, it was of no avail in preventing ulceration of the cornea in one case referred to by Boissou, that of Peugnier. I am not aware of this operation having been performed in any case with the express purpose of saving the eyes, but in one case it was recommended by Dr. G. Mackay to Mr. F. M Caird, who, however, preferred to remove one lobe of the thyroid gland, which he did and with a most beneficial effect on the eyes.

The ligature of three of the four arteries to the thyroid gland is an operation which has met with a measure of success, but there may be a difficulty in reaching the arteries behind the enlarged thyroid gland. There remain to be considered the effects of removal of a portion of the enlarged thyroid gland. A considerable number of these operations have now been performed and have been collected, analysed, and considered by various writers. Allen Starr, writing in 1896, had collected 190 cases; 74 of these cases were reported as completely cured; 45 as improved; three as not improved; 23 patients died immediately or within a few hours of the operation; and of the remaining 45 no final report was available.

The occurrence of sudden death immediately after the operation or within a day or two of it is, as Allen Starr well says, a fact of very serious import; it constitutes a most serious bar to the performance of what would otherwise be a promising operation, and it is therefore well worth while to consider its cause. "Death after these operations," says Starr, "is not due to hæmorrhage or to any want of aseptic precautions. In all the cases reported there has been a sudden rise of temperature to 105°, 106°, and 107°; a very rapid pulse (180 to 200); extreme nervous excitement and restlessness with great anxiety and distress, profuse sweating, and finally collapse and death from heart failure." These distressing calamities have been attributed to various causes. Sometimes the anæsthetic has been blamed, but many of the deaths occur rather late for that, especially in the cases in which chloroform has been administered. It must, however, be admitted that animals suffering from athyroidea die very readily from chloroform unless it is administered with extreme caution If the deaths are due to the general anæsthetic cocaine or eucaine can be, and indeed sometimes is, substituted. It seems, however, more probable that the fatal results are in some way due to the operation itself, and if that be so the most obvious and natural view is that the removed lobe is necessary to the life of the patient Another view is that something goes wrong during the progress of the operation. It has been thought that the symptoms are caused by the handling of the lobe during removal, by which its secretion would be pressed into the lymphatics and thus into the circulation, and that the incision into the thyroid tissue has led to a leakage at the time of operation and afterwards into the cavity of the wound from which it has been absorbed. In this way the cause of death would be an excess of thyroid secretion (normal or abnormal) in the circulation—hyperthyroidisation, in fact Consideration, however, of the symptoms themselves would lead to the opposite view—that they are due to too little secretion in the circulation. Attacks of palpitation and dyspnœa, followed by collapse and death, we have seen to occur both in Sir William Stokes's case of acute athyroidea and in experiments on the lower animals. It is, of course, possible that in Graves's disease we have to do with an excess of one constituent of the secretion and a diminution of another, and that this latter condition is aggravated by the partial removal and constitutional disturbance during and after the operation.

Whatever may be their explanation, these cases are, no doubt, a great objection to operating, but they need not wholly turn us from that idea. It must be remembered that cases of sudden death occur in Graves's disease among patients who have not been operated on; they are mentioned in all text-books, and, in fact, are not uncommon. Also the prognosis to life in this disease is not at all satisfactory; death has been recorded as occurring in six weeks from the onset, and even in the favourable surroundings of a hospital deaths do occur from time to time, sometimes suddenly without apparent cause, sometimes from diarrhœa or some complication. Indeed, it is from the cases of those patients who die in hospital that our knowledge of the pathology is mainly derived. What may be the subsequent history of the patients who return home is not certainly known; some of them continue ill for a long time, others may no doubt improve, but it has been denied that cases of Graves's disease ever completely recover, at least without operation. Of the 190 cases of operation collected by Allen Starr 74 are reported as completely cured and 45 more as improved; these results are very encouraging, as are also the records of individual cases One of the earliest operations in Graves's disease was performed by Lord Lister when he was at the Edinburgh Infirmary. The patient was a woman, aged 26 years. She had been ailing for five years, during the last three of which she had had well-marked symptoms of Graves's disease, for which, presumably, she had had medical treatment. It was intended at the operation to remove the whole of the thyroid gland (this was before the dangers of so doing were recognised), but this probably was not done. Before operation the pulse-rate was 130 and the pulse was irregular; five days after the operation the pulse had fallen to 74 and was regular, and in a few weeks the exophthalmos was much reduced. The patient was seen again 10 years later, at which time she was suffering from phthisis. The exophthalmos was slight, the excitement of the circulation was nearly gone, and there was no thyroid tumour, but a slight eminence in the middle line suggested that a portion of the isthmus had been left at the operation; there were no symptoms of myxœdema.

As another example a case recorded by Reidel may be mentioned. The patient, a female, aged 20 years, had suffered for years from a goitre and during the later years there had been in addition palpitation so severe that she complained that her heart seemed trying to jump out of her chest. Exophthalmos was so extreme that it was noticed in the street, and the patient had become extremely nervous, depressed, and much emaciated. The right half of a parenchymatous *goitre was excised; the case did* well. *Three* years after the operation the patient was seen again; she was in good spirits and in full enjoyment of life. The palpitation was completely cured, she could walk for an hour at a stretch, and at a ball could take part in every dance. The exophthalmos and emaciation were gone.

A case in a male under Sir William Stokes's care may also be cited. The patient was a farmer, aged 32 years, who seven years previously had had a fright caused by seeing a friend killed by a threshing machine. Three weeks after this he noticed a slight enlargement in the neck, which was followed by palpitation and exophthalmos. These symptoms continued, together with other characteristic symptoms. Six years later he was admitted to hospital where under treatment he improved, but on returning home he relapsed and was again admitted to hospital, when Sir William Stokes was asked to see him Operation was decided upon and a central tumour of the size of a Tangerine orange was removed, together with part of one lobe. In a few weeks there was marked alleviation of all the symptoms and the patient ultimately recovered. Two years after the operation there had been no recurrence of the symptoms.

My own experience is confined to two cases. In the first the patient was very ill, palpitation and dyspnœic attacks being the main symptoms. As she continued to get worse operation was decided upon and the right lobe of the enlarged thyroid gland was removed. The patient got much better and all the symptoms were greatly relieved, but there are still (it is now eight years since the operation) symptoms of the disease. The other case was much less severe. The symptoms, however, did not yield to medical treatment, and as there was a unilateral swelling operation was decided upon. The swelling proved to be due to an adenoma which was excised. The symptoms completely disappeared; indeed, the tremors had gone the day after operation. On microscopical examination the adenoma was seen to have undergone hypertrophic changes. Great improvement in Graves's disease after removal of an adenoma has been noticed before. Murray records, too, a case in which the symptoms almost completely disappeared after drainage of a cyst in a goitre. In the present case the adenoma was found to have undergone the usual changes seen in Graves's disease; the rest of the thyroid gland was little if at all enlarged. Many other cases very encouraging as to operation could be cited. Probably the lesson to be learnt from the fatal cases is not that operations should not be performed, but that they should be performed earlier.

THE SURGICAL TREATMENT OF CHRONIC ULCER OF THE STOMACH.[1]

By A. W. MAYO ROBSON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE GENERAL INFIRMARY, LEEDS; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

THE treatment of gastric ulcer is at first essentially medical and when properly carried out and for a sufficient length of time it is usually completely successful. Leube says that one-half or three-fourths of all cases will be cured by four or five weeks of treatment, but that if not cured in that time they will not be cured by medical treatment alone—a view which, I feel sure, is a true one. Unfortunately, however, in many cases treatment is stopped as soon as relief from pain is obtained and long before the ulcer is healed. In some cases this may be due to the uncertainty of diagnosis or from the impatience of the patient; perhaps in others to ignorance as to how long it takes to secure the healing of a gastric ulcer. The earlier in the course of the disease that radical treatment in the shape of dieting and rest is adopted, the less prolonged will the treatment need to be and the more likely is it to be effectual. But probably the very earliest time that a patient should be allowed to be out of bed is from a fortnight to a month after all pain and tenderness have disappeared Failing this thorough treatment relapses will be certain to occur and in the long run complications will supervene or the ulcer will become chronic, when, though medical treatment may relieve in some cases, cure can be looked for in the greater number only by surgical methods.

In considering the treatment of ulcer of the stomach it is useful to hold in view the course of an ulcer of the leg, which directly the healing stage has arrived becomes free from pain; but this indicates neither that healing is completed nor that care may cease, and should treatment be abandoned and the ulcer become chronic, though it may even then be painless, it is at any time liable to become inflamed or to extend; moreover, the surrounding tissues become infiltrated with lymph, which tends to organise, and this in a hollow viscus soon ends in stricture, as in the leg it tends to drag on the surrounding skin and produce constriction of the limb

The surgical treatment of intractable or relapsing gastric ulcer is in the greater number of cases the only satisfactory method of dealing with these refractory cases, and operation should be resorted to at a much earlier period than has hitherto been the custom, and always before the patient is so far reduced by pain and starvation or the supervention of serious complications that weakness and anæmia render any operative procedure hazardous. Ulcer of the stomach is a much more serious matter than is generally recognised, for according to various authors it has a mortality, when treated by general and medical means only, of from 20 to 50 per cent. Dr Einhorn, in his well-known work on Diseases of the Stomach (p. 223), says: "At first glance it would appear that the prognosis of gastric ulcer is quite good, especially nowadays, when the diagnosis of the affection is usually made at an early date" However, if we take into consideration the tabulated statistics given by Debove and Rémond (p. 276) in reference to the outcome of all cases of ulcer we become more careful in our favourable predictions. This table gives in 100 cases of ulcer: perfect cure, 50; perforations and peritonitis, 13; foudroyant hæmatemesis, five; pulmonary tuberculosis, 20; inanition, five; and different complications, seven The excuses of a few years ago that there is a great responsibility in recommending surgical treatment either from the uncertainties of diagnosis or from the risk of operation can no longer avail, since the diagnosis of gastric ulcer, thanks to the researches of Ewald, Hemmeter, Einhorn, and others, has been brought to a greater state of perfection than exists in many other obscure diseases, where radical treatment has to be adopted on much more slender foundations; and fortunately, now that the mortality in operations for simple diseases of the stomach, excluding perforation and hæmorrhage, has been reduced in the hands of experienced surgeons to 5, or even less than 5, per cent., the great risks of surgical treatment cannot be advanced even by its most ardent opponents.

---

[1] A paper read before the American Surgical Association on May 5th, 1901.

We have to consider, not only the treatment of gastric ulcer itself, but also that of its complications, which are no less numerous than serious, and before describing each separately it may be as well to name them collectively. They are as follows: (1) local peritonitis or perigastritis ending in adhesions; (2) local peritonitis ending in suppuration and a localised abscess; (3) subphrenic abscess; (4) abscess of the liver, pancreas, or spleen; (5) fistula between the stomach or pylorus and adjoining organs or with the surface of the body; (6) acute perforation of the stomach wall; (7) general peritonitis; (8) hæmatemesis and melæna; (9) dilatation of the stomach; (10) tumour of the stomach or the pylorus; (11) cicatricial stenosis of the pylorus; (12) hour glass stomach; (13) spasm of the pylorus producing intermittent narrowing (Reichmann's disease); (14) atonic motor deficiency; (15) severe gastralgia; (16) persistent vomiting; (17) tetany; (18) acute or chronic pancreatitis; (19) profound anæmia resembling the pernicious form; (20) pressure on, or stricture of, the bile-ducts with jaundice; (21) catarrh of the gall-bladder from adhesions producing attacks like those of cholelithiasis; (22) great loss of flesh and strength ending in phthisis; and (23) cancer secondary to ulcer ("ulcus carcinomatosum").

We are not prepared to subscribe fully to the views of Tricomi,[2] who draws a parallel between the treatment of hernia and that of ordinary gastric ulcer and proposes that as hernia is treated radically with success, so gastric ulcer should be treated radically by the performance of gastro-enterostomy. Heydenreich[3] argues: "The death-rate from all cases of gastric ulcer is from 25 to 30 per cent., but from gastro enterostomy only 16·2 per cent.; therefore, the operation has less danger than the disease." The question of medical *versus* surgical treatment in this class of cases is one, however, that can be much simplified by a careful study of statistics. At the time I delivered the Hunterian Lectures in March, 1900, I had been able to collect from various sources 188 operations on the stomach for gastric ulcer (excluding those for perforation and hæmorrhage) of which 157 recovered and 31 died, thus giving a mortality of 16 4 per cent. These included 34 personal cases.

Now, although the deaths from gastric ulcer medically treated averaged 25 per cent. and those from even the worst and most inveterate cases of ulcer when treated surgically only 16 per cent at the time of those lectures, yet the difference did not then appear so great as to make it desirable or prudent very strongly to advocate surgical treatment until the disease had become chronic or until serious complications had ensued. To-day, however, the facts are very materially altered by the all round improvement in operations on the stomach, and the contrast of 25 per cent of deaths in cases treated medically, and 5 per cent. as shown in our latest statistics in those treated surgically, in the worst and most complicated cases, is so striking that we feel it incumbent to urge most strongly that although cases of gastric ulcer should first be submitted to medical treatment, yet if such treatment fails to cure in a reasonable time, or if relapses occur on the resumption of solid food, then surgical should take the place of medical treatment, for it is unfair to the surgeon to hand over to him almost moribund cases, and it is unjust to the patients to persist in dosing them with medicine, or otherwise treating palliatively cases that can only be benefited or cured by surgical means.

Operative treatment.—Before the abdomen is opened it is quite impossible to say what operation or operations will be required and the surgeon must be prepared to adapt himself to circumstances on discovering the position of the ulcer and the conditions associated with it, especially as to the presence or absence of adhesions and other complications. Any one of the following operations, or a combination of one or more, may be called for in each individual case: exploratory gastrotomy; gastro-enterostomy to secure physiological rest to the stomach and relieve the hyperchlorhydria, or in other cases to short circuit a stenosis; excision of the ulcer; pylorectomy; pyloroplasty; gastroplasty; gastrostomy; gastrolysis; pylorodiosis; and gastroplication.

The preparation of the patient—It has been the custom with many surgeons to put stomach patients through a long course of preliminary treatment, such as frequent lavage of the stomach and abstention from food before operation. This, as a rule, is quite unnecessary and certainly inadvisable in the greater number of cases, first because the treatment is depressing and debilitating in the case of patients already exhausted by a long illness; secondly, as proved by Dr. Harvey Cushing's bacteriological investigations, the stomach contents speedily become aseptic if the mouth be cleansed and aseptic foods administered; and, thirdly, as proved by ample clinical experience, elaborate preliminary treatment is unnecessary to success. If the stomach is greatly dilated and the contents are foul, then lavage with simple boiled water night and morning is adopted for two days before operation. The careful cleansing of the mouth and teeth and the administration of foods sterilised by boiling is advisable. The last meal is given the night before, about 12 hours; the stomach is washed out about two hours and a nutrient enema given about an hour before operation. In other cases no lavage is adopted, but the same care is exercised in cleansing the mouth, giving sterilised food, and administering a nutrient enema consisting of one ounce of brandy, one ounce of liquid peptonoids, and 10 ounces of normal saline solution. Every patient is enveloped in a suit of cotton wool made by the nurse out of Gamgee tissue, and each has an injection of 10 minims of liquor strychninæ, B.P., administered subcutaneously before the operation is begun. The preparation of the skin and other aseptic details of the operation differ in no respect from those observed in operations generally.

Exploratory gastrotomy, or opening the stomach by a free incision in its anterior wall, is an operation occasionally called for in the surgical treatment of ulcer: (1) in order to verify the diagnosis of ulcer when there is so much thickening of the stomach walls as to suggest the presence of cancer; (2) when, although the symptoms have pointed to ulcer as the cause of the gastric trouble, the stomach on exposure betrays no evidence of puckering or other characteristic signs, and when in order to verify the diagnosis and ascertain what is best to be done it is felt desirable to examine the interior of the organ; (3) in certain cases of gastrorrhagia it is desirable to perform exploratory gastrotomy in order to find and to ligature the bleeding vessels or to otherwise arrest the hæmorrhage; and (4) it necessarily forms part of any operation for the excision of ulcer of the stomach. It is not necessary for me here to enter into any detailed description of the operation, which must be so familiar to all my hearers and which requires to be varied according to the object in view. The following are examples of exploratory gastrotomy for ulcer.

CASE 1—The patient was a man, aged 38 years There were symptoms of chronic ulcer extending over several years. On exposure of the stomach there was no evidence on the surface to indicate the accuracy of diagnosis Exploratory gastrotomy was performed. A large ulcer, one and a half inches by three inches, on the posterior wall of the stomach was discovered. Posterior gastro-enterostomy was performed and recovery ensued.

CASE 2—This was a case of acute gastrorrhagia There was no evidence on exposing the stomach. Exploratory gastrotomy was performed. Numerous bleeding ulcers were seen, two of which were bleeding freely and were ligatured *en masse*. Gastro-enterostomy was performed and recovery ensued.

Excision of the ulcer is, as a rule, unnecessary, but not always to be avoided, as in some cases of bleeding ulcer and in others where the thickening and induration render it difficult to decide on the absence of malignant disease. This was the case in a man, aged 54 years, on whom I operated in 1891, when finding the pylorus the seat of diffuse induration excision of the whole indurated area was performed successfully. A careful examination of the removed mass showed that the growth was inflammatory around a chronic ulcer. In another middle-aged man where the diffuse induration was suggestive of cancer the pylorus was opened and a deep ulcer on the posterior wall successfully excised, the edges of the original incision as well as the margins of the posterior wound being brought together in a direction transverse to the axis of the pylorus over a bone bobbin, as in the modified operation of gastro enterostomy. Rydygier prefers excision of the ulcer to gastro enterostomy, because he believes that carcinoma not infrequently develops in the scar of an old ulcer It is impracticable to give any specific description of the operation of excision of an ulcer, seeing that the procedure will vary according to its size and position. After excision of an ulcer the bleeding from large vessels must be controlled by ligature, but the oozing from the smaller vessels will be stopped readily by the continuous suture employed to bring together the edges of the wound. If the excision involve the serous coat a Lembert's continuous stitch with a silk or celluloid suture will be necessary. Should an excision have been near the pylorus the line of suture must be placed transversely to the axis of the canal so as to avoid stricture. The following cases are examples of gastric ulcers treated by excision.

[3] Semaine Medicale, Feb 2nd, 1898

CASE 3. *Ulcer of the pylorus, stenosis, dilatation of the stomach, excision of the ulcer and pyloroplasty.*—A man, aged 38 years, was admitted to the Leeds Infirmary with the history of stomach trouble for 13 years. Pain after food and vomiting were the initial symptoms. Severe hæmatemesis occurred six years after the commencement of symptoms. Great loss of flesh and weakness were followed by inability to work, although he had stomach lavage and other appropriate treatment. On admission the patient was very thin and profoundly weak. He weighed 8 stones. A swelling could be felt below the right costal margin. The stomach reached three inches below the umbilicus and there was visible peristalsis. Free HCl was present. Operation was performed on Nov. 15th, 1900. The pylorus was found much thickened, forming a nodular swelling adherent to the gall-bladder and liver and to the abdominal wall by omental adhesions. After separating the adhesions a small perforation was discovered in front of the pylorus, evidently the site of a perforation which his medical man, who was present, said he remembered occurring some months previously and which was then treated successfully by rest and rectal feeding. The pylorus was freely laid open and found to be the site of a round perforating ulcer in front and another on the posterior wall—the latter had perforated into the substance of the pancreas; both were excised, thus practically constituting a pylorectomy. The edges of the posterior wound were brought together transversely to the axis of the stomach. The anterior wound was prolonged into the duodenum and stomach and its edges were brought together transversely to the axis of the stomach over the bone bobbin, thus leaving a capacious channel between the stomach and duodenum surrounded by healthy mucous membrane. Recovery was uninterrupted and he was discharged on Dec. 12th, weighing 8 stones 5 pounds. On Jan. 9th, 1901, he returned to report himself well and then weighed 9 stones 11 pounds.

CASE 4. *Pyloric ulcer treated by excision of the ulcer and pyloroplasty.*—The patient was a woman, aged 44 years. She had been well till two years ago when she had colic and loss of flesh. Under treatment she recovered and regained some of her lost weight. On Sept. 15th, 1897, there was a recurrence of attacks similar to that of a year before, but with pain at the right side over the pylorus. There were loss of weight and of strength. The patient had for some time been an invalid and had been continuously under medical treatment for months. Her weight was 5 stones 11 pounds. There was visible peristalsis towards the pylorus which was fixed to the gall-bladder, but no pain or tenderness. The liver was two inches below the costal margin, but not nodular; no jaundice was present. Operation was performed on July 23rd, 1898. An ulcer at the pylorus was found adherent to the liver which formed its floor. There was stenosis of the pylorus. Pyloroplasty was performed after excision of the ulcer, the opening being sutured transversely over a bone bobbin. On Dec. 3rd the patient had gained 1 stone 8 pounds in weight. There was no trouble in digesting anything. On Dec. 23rd, 1899, she was reported as "very well" and of normal weight.

The operation for pylorectomy for ulceration of the pylorus may be conveniently mentioned under the heading of excision of ulcer. Dr. Rodman[4] has collected from literature and personal correspondence detailed reports of 40 pylorectomies, partial gastrectomies, and excisions for ulcer, with six deaths. This includes cases since 1881, but the later operations under improved technique contrast favourably with the earlier ones. I have myself performed the operation of excision of gastric ulcer six times, all the patients recovering. Nevertheless, the mortality after excision will probably always be higher than the more simple operation of gastro-enterostomy. The more severe and radical operation should therefore be reserved for cases that are not suitable for the less severe operation or in which the suspicion of cancerous degeneration is entertained and cannot be disproved on naked-eye inspection. The following case is an example.

CASE 5. *Tumour of the pylorus and chronic hæmatemesis due to ulcer.*—In 1891 I was asked by a medical friend to see a man, aged 54 years, who for six months had suffered from pain coming on an hour after food and more recently from vomiting blood of coffee-ground character in considerable quantities, so that he was not only reduced in flesh and strength but had also been rendered profoundly anæmic by the loss of blood. A tumour of the pylorus could be easily felt and the stomach was markedly dilated. As he was rapidly losing ground an operation was performed and the pylorus was found to be thickened and nodular, with adhesions to the liver and omentum. After separating the adhesions the pylorus was excised and the opening of the duodenum was fixed to the opening in the stomach by means of two lines of sutures without the use of a bobbin, the rest of the stomach aperture being closed by a double layer of sutures. The tumour proved to be inflammatory around an open ulcer which had been the source of the hæmorrhage. The bleeding was not repeated and the patient rapidly gained flesh and returned home within the month.

The subsequent history of this case is interesting on account of cicatricial contraction of the new pyloric aperture which led to the invention and employment of a decalcified bone bobbin to act as a temporary splint over which to apply the sutures and thus to secure a large aperture which has little tendency to contract.

Gastro-enterostomy, in the absence of special complications, is the operation to be relied on in the treatment of ulcer of the stomach. It acts by securing physiological rest by means of drainage, thus allowing the ulcer to heal without being subjected to the irritation of acid secretion, accumulation of food, or frequent stomach movement. It also, while remedying the hyperchlorhydria, relieves pyloric spasm and while preventing stagnation of fermenting fluids materially diminishes gastric dilatation. The posterior operation is the one I personally prefer, the junction of the posterior wall of the stomach with the first part of the jejunum being effected by two continuous sutures with or without a decalcified bone bobbin. The use of a bone bobbin not only secures an ample and immediately patent opening between the two viscera for the passage of the stomach contents, but protects the line of union from the irritation of the stomach contents. The whole operation can be easily completed in half an hour, and it may even be done in half the time. Along with my colleague, Mr. Moynihan, I have given my full experience of the operation and of stomach surgery in general in book form, now in the hands of the publishers. Our experience with the posterior operation has been very favourable, not only in the rate of recovery of the patients, but in the smoothness of the recovery, many of the patients recovering without even once vomiting, and only on two occasions have we seen regurgitant vomiting of bile, which in the anterior operation is much more frequently seen and at times becomes serious or even leads to a fatal issue. We have performed the posterior operation on 40 patients with two deaths, or an average mortality of 5 per cent., but as the deaths were from more or less accidental causes which should be avoided in the future, and occurred respectively on the tenth and eleventh days after operation, during the whole of which time the patients had been able to take and to assimilate food, the gastro-enterostomy *per se* cannot be blamed for the result, which might under similar circumstances have occurred after any operation.

Dr. Fantino[5] examined Professor Carle's cases of gastro-enterostomy as regards the following points: (1) changes in the peristalsis of the stomach; (2) the ability or non-ability of the new sphincters to close the outlet; (3) the capacity of the stomach; and (4) the secretion of hydrochloric acid. In the cases examined the operation immediately improved the peristaltic power of the stomach, though it did not render it normal. The stomach could generally empty itself, but did so gradually. Systematic examinations of the stomach contents were made after test meals, &c., and they showed that after an irregular period the stomach regained completely its power of emptying itself; in fact, as a rule, after gastro-enterostomy the stomach will be found practically empty in from three to five hours after a meal. Generally, it was found that the stomach decreased in size soon after gastro-enterostomy, so that the formerly distended organ became normal in size. Examination of the stomach by means of distension with carbonic acid and by other methods showed that a sphincter was developed at the new opening and that its power increased with time. The secretion of hydrochloric acid after operation was studied. In cases where there was formerly hyperacidity this condition was lost, and though the degree of acidity in any individual case varied from time to time, yet these variations did not depart from physiological limits. In the same examinations it was found that regurgitation of bile into the stomach took place, but it was of no importance so long as the outlet from the organ was sufficient. In cases of hyperacidity and anacidity there was no change in the gastric juice after operation, showing clearly that this condition is not dependent on obstruction but on previous changes in the mucous membranes, these changes being probably in the nature of an atrophy of the peptogastric glands. The following cases are given as examples of the treatment of gastric ulcer by gastro-enterostomy.

---

[4] Philadelphia Medical Journal, June 9th, 1900.

[5] Archiv für Klinische Chirurgie, Band xlix., pp. 1 and 2.

CASE 6.—The patient was a woman, aged 32 years. Pyloroplasty was performed during active ulceration of the pylorus in December, 1895. There was great relief for a time, but later there were recurrence of dilatation, vomiting, pain, and other symptoms. There was very considerable loss of flesh. The patient was thin and anæmic; the pulse was feeble and rapid; there was marked dilatation, the stomach reaching well below the umbilicus. Anterior gastro-enterostomy was performed on Oct. 4th, 1988 (a bone bobbin was employed) In October, 1899, the patient was well and active. In February, 1900, she had gained 1 stone 10 pounds.

CASE 7.—The patient was a man, aged 28 years, who had a pyloric ulcer and a tumour of the pylorus. Two years ago he weighed 12 stones 12 pounds; he now weighed 9 stones 6 pounds. He had pain two hours after food. For the last two months there had been vomiting on an average five times a week; twice there had been coffee-ground vomit There was enormous dilatation of the stomach. The pyloric tumour was moveable and there was visible peristalsis. Operation was performed on August 4th, 1899. There was a large mass at the pylorus, evidently thickening due to active ulceration; the glands were large but not matted. Anterior gastro-enterostomy was performed (a bone bobbin was used) On the 27th there was good recovery and the patient weighed 9 stones 7 pounds On Sept. 9th the patient weighed 10 stones 13 pounds and could eat anything. He was well in 1901.

CASE 8.—The patient was a man, aged 31 years, who had an extensive ulceration of the stomach with a large tumour. He had suffered from dyspepsia for 17 years, which had been more severe during the last 20 months. 16 months ago vomiting recurred and from the outset large quantities were ejected but never containing blood. There was recurrence occasionally of similar attacks, which were always relieved by treatment. In December, 1897, the stomach reached the pubes and visible peristalsis was seen. Relief followed dieting and lavage till March, 1898, since which time pain had been almost constant. The pain was not materially worse after food, nor was it relieved by vomiting. The loss of weight was from 10 stones to 8 stones 6½ pounds. There was great feebleness. Operation was performed on May 6th, 1898. There was a large irregular tumour at the pylorus and along the lesser curvature, but the glands, though large, were discrete. Anterior gastro enterostomy was performed, a bone bobbin being employed The patient was 8 stones in weight when he left the home on June 7th. On August 17th he weighed 9 stones 3 pounds. A letter, dated Feb. 12th, 1900, says: "My health continues perfect. I have not lost a day's work through illness since I recovered."

CASE 9.—A woman, aged 32 years, was sent to me with a history of stomach symptoms extending over several years. She had had hæmatemesis in 1892 and in 1896, since which time she had suffered from flatulency and pain after food. For two years epigastric pain was constant, but it was increased by taking food. A year ago she had vomited daily; then she had relief for a time, but for some months only milk could be retained. Epigastric tenderness was well marked and on distending the stomach with CO$_2$ it reached half an inch below the umbilicus and far over to the right of the middle line. On Oct. 5th, 1900, posterior gastro-enterostomy was performed, a bone bobbin being employed. Recovery was uninterrupted. The patient returned home within the month, taking solid food without any discomfort and gaining flesh. On Nov. 8th Dr. A—— wrote: "I have seen Miss —— since her return and there is every reason to be pleased with her condition. She has lost all her pain and is taking food well. Allow me to thank you for her restoration to comparative health." In February, 1901, her weight was 8 stones 6 pounds; at the time of operation it was 6 stones 12 pounds.

CASE 10.—The patient was a man, aged 52 years, who began to suffer in 1897 from symptoms of ulcer of the stomach, which were relieved by restricted diet and general treatment, but in July, 1899, the symptoms returned with great loss of flesh and strength. Well-marked dilatation of the stomach was discovered and operative treatment was advised. Lavage and other treatment were carried out in London and in Scotland, but without material improvement When first seen by me there was visible peristalsis with well-marked stomach splash and a tender spot under the right costal margin. Although tall the patient only weighed 8 stones 10 pounds and he was extremely weak and pallid Operation was performed on Oct. 12th, 1900. Hour glass stomach was found, but the stricture was not extreme There was puckering on the anterior wall of the stomach with well-marked thickening. Free HCl was discovered in the stomach contents. Posterior gastro-enterostomy was performed. Good recovery followed. On March 4th, 1901, the patient wrote saying: "I am pleased to be able to tell you that I have had no return of my former complaint and that I eat, drink, and sleep well. Have got back to my former weight."

CASE 11.—The patient was a man, aged 45 years, residing at Batley. He gave the history of pain about an hour after food, with great loss of flesh, which he had experienced for two years. For nine months he had vomited every day or every second day a large quantity of yeasty material but no blood, though he was very anæmic. There were well marked signs of dilatation, with tenderness over the pylorus. Operation was performed on June 12th, 1900. On opening the abdomen the pylorus was found to be much thickened and adherent, forming a tumour, and through the centre of the mass a No. 10 catheter only could be passed over a roughened, ulcerated surface. A posterior gastro-enterostomy was performed. With regard to the after history an uninterrupted recovery followed. Food was begun on the second day and solids could be taken in the second week without pain. The patient rapidly gained flesh and strength and was now well.

The following case illustrates the value of gastro-enterostomy in acute hæmatemesis.

CASE 12. *Chronic ulcers; hæmatemesis; gastro-enterostomy.*—A farmer residing in Essex was sent to me on March 26th by Dr. A. J. T. White who kindly furnished the following history. "I first saw Mr. —— five years ago; he had then occasional pain in the epigastrium, with much flatulence and at times vomiting. This kept on at intervals more or less for three years. Eighteen months Dr G—— saw him with me. At that time instead of his former weight of 16 stones he only turned the scale at 12 stones. He then improved gradually for about three months and gained about a stone in weight. Six months later, or about a year ago, he, while out driving, had some abdominal pain and vomited considerable quantities of blood. He continued being sick and suffering for some time with slight hæmatemesis and melæna, but again improved. About three or four months ago he got worse and has been vomiting and suffering considerable pain on and off ever since. I have very little doubt but that this original trouble was gastric ulcer, but my fear now is lest malignant ulceration should have supervened, and some time ago I asked him to see you. He could not go then as he had various business matters to set right, but now is willing. He is a man of iron will and constitution though terribly pulled down." On the patient's arrival in Leeds he went direct to a surgical home, his weight then being 10 stones. He was then suffering severe pain but was able to take a little milk, which was, in fact, the only form of food which he had been able to digest for a long time. Within a few hours he was seized with violent hæmatemesis and vomited five pints of clots and dark fluid mixed with mucus. Rectal feeding was at once adopted and an ice-bag was applied to the epigastrium. The next day much coffee-ground material was vomited and on the third day the bleeding ceased. An operation, which was clearly demanded, was arranged for March 22nd, but on the night of the 21st he again vomited two pewtersful of pure dark blood which clotted soon after being vomited. The stomach was quite empty of food, as after the night of his admission feeding had been entirely rectal. He was now extremely weak, but as the vomiting and bleeding were continuing Dr. White agreed with me that it would be better not to postpone operation, for he was rapidly losing ground and clearly could not stand a greater loss. An hour before operation he vomited blood freely again. On the morning of the 22nd, on opening the abdomen, the lesser curvature of the stomach was found to be much indurated, forming a tumour. There was also much puckering of the surface of the stomach and the glands in the greater and lesser omentum were enlarged but discrete. A posterior gastro-enterostomy was performed, a bone bobbin being used. In order to guard against shock he was enveloped in cotton wool, had 10 minims of liquor strychninæ (B.P.) given subcutaneously before operation, and had a pint of saline fluid with an ounce of brandy given into the bowel. Immediately after operation, which was finished within the half hour, nearly a pint of saline fluid was injected into the subcutaneous tissues of the axilla and another pint, together with an ounce of brandy, was administered per rectum. During the day three injections of five minims of liquor strychninæ were given and the rectal enemata were repeated. Very little shock was felt, and the after-progress was uninterrupted The bowels were moved on the third day, and the wound was dressed and found healed on the tenth. No more blood was parted with, and stomach feeding was begun four days after operation. By the end of the week he was taking as much as five pints of fluid nourishment in the 24 hours He said he had never had any pain since the operation and was feeling better than he had done for a long time. He had lost all the acid eructations, the constant burning at the epigastrium, and the flatulency. He returned home within the month very well, and, as showing the state of his digestion, he had gained 4 pounds in the week before he left the surgical home.

Pyloroplasty as a curative measure in this class of cases has certain very definite limitations, but where it is feasible it is a method of great utility which can be performed rapidly and with very little exposure of viscera. Pyloroplasty, if the pylorus be stenosed, free from extensive adhesions, easily drawn forward and not actively ulcerating, is a simple and short operation, and in quite a number of cases of both gastric and pyloric ulcer I have found it to answer well It must not be relied on, however, where active ulceration of the pylorus itself is found, unless at the same time the ulcer be completely excised; otherwise cicatricial contraction will follow. It acts in the same way as does gastro-enterostomy by affording a free exit to the stomach contents and thus securing physiological rest to the stomach. The histories to be related exemplify the complete success which attended the operation in appropriate cases and also the disappointment which followed its employment in one of the earlier examples which owing to inexperience was not properly selected.

Professor Carle and Professor Fantino[6] compare the operation of gastro-enterostomy and pyloroplasty. Out of 14 cases in which the latter operation was performed only one died. The results of pyloroplasty, as regards function, have been little noticed in literature. To the author's 14 cases three may be added where the operation was by tearing, but the results were the same. In all the 17 cases the results were excellent, and in 13 of them they were perfect and permanent, as it is now from three to seven years since operation. In these the condition of the secretions and of the peristaltic power of the stomach was the same as after gastro-enterostomy for non-malignant stenosis Diminution in the size of the stomach was not so marked as would be expected in the presence of such remarkable recovery of the general health and of the stomach's power to empty itself. In all cases, with one exception, the gastric capacity was more or less diminished, but in no case did it become normal in size. A few cases must be excepted where operation was performed for hyperacidity with gastric atony. In these, four or five months after operation, there were delayed evacuation of the stomach and a feeling of weight. Although the general improvement was considerable, yet the authors were persuaded that a posterior gastro-enterostomy would have given better results. In one of the cases a subsequent gastro-enterostomy gave a perfect recovery. In cases where there was hyperacidity before the operation there was a rapid return to the normal, but *not to below* normal, as was found after gastro-enterostomy. The authors believe that the rapid and great diminution in hydrochloric acid after the latter operation is due to the very rapid evacuation of the stomach after a meal, and they do not deny the possible influence of a regurgitation of bile into the stomach Both these conditions are absent after pyloroplasty, hence the difference in secretion

In cases of hyperacidity and anacidity operation produced no change in this particular and yet health was restored. The results of pyloroplasty may be summarised: (1) regurgitation of bile into the stomach is prevented; (2) secretion of hydrochloric acid when it has been excessive becomes normal; (3) if the secretion of hydrochloric acid has been diminished or absent before operation it remains *in statu quo* after operation; (4) if there has been primary gastric atony peristalsis is but little improved; (5) this function improves rapidly or reaches perfection if the muscular contractility has been normal or increased, and when the obstruction was due to fibrous stenosis or pyloric spasm; (6) in all such cases evacuation of the stomach is accomplished in its physiological period (only in rare cases, and these only in the first months, after operation may it be delayed); (7) the capacity of the stomach always decreases but rarely becomes as small as normal; and (8) the pylorus recovers tone.

Points of difference between the results of pyloroplasty and gastro enterostomy are: (1) the absence of regurgitation of bile and hence the absence of any possible biliary influence on the gastric secretions; (2) the evacuation of the stomach is not accelerated, hence the difficulty the stomach has in reaching its normal size; and (3) the slight or negative result obtained by pyloroplasty in obstruction from primary gastric atony compared to the positive results from posterior gastro enterostomy.

Pyloroplasty is too dangerous in cases where there is extensive induration of the tissues, much peripyloritis and adhesions to liver, gall bladder, colon, &c., and in cases of duodenal stenosis It is indicated in cases of spasmodic stenosis and in slight annular stenosis from ulceration accompanied by muscular hypertrophy.

In the Hunterian Lectures I collected 318 cases of pyloroplasty from all sources, of which 269 recovered, which equals a mortality of 15·4 per cent; this included 14 cases of the lecturer's, of which 12 recovered—a mortality of 14·2 per cent. As in the earlier operations many were performed on cases that would be now treated by gastro-enterostomy the mortality in properly selected cases should not exceed 5 per cent. at the outside estimate, and of the 12 cases I have operated on since 1897 there is no fatality to record.

CASE 13—The patient was a woman, aged 29 years. She had had "spasms" for 10 years, but the pain was more on the left side She was attacked two or three times a week; the attacks would start without apparent reason and last an hour or two but they might persist for 24 hours The patient was relieved by vomiting She had severe cramps in the legs and a loss of 2 stones in weight; there was no jaundice but marked constipation The right rectus was rigid; there was no rigidity, but tenderness to the left. Dilatation of the stomach was well marked on Nov. 22nd, 1895 She was relieved under treatment which was followed by a relapse; she was now vomiting daily Her weight was 9 stones. The operation was as follows The adhesions of the pylorus were separated There were active ulceration at the pylorus and a tight stricture. Pyloroplasty was performed, a bone bobbin being used On July 24th, 1896, her weight was 9 stones 5 pounds and she was very much better. She had a relapse in 1898 possibly from recurrence of the ulceration. I then performed gastro enterostomy She was quite well in 1900 and her former weight was fully regained

CASE 14—The patient, a man aged 52 years, was seen on Jan 13th, 1897. He had an ulcer of the pylorus with stricture. He had had bad health for 20 years with dyspepsia which had become worse since he had enteric fever nine years before The last two years he had been much worse; he had pain, sickness, and vomiting from two to three hours after meals relieved by vomiting of large amounts. He never vomited blood. There was loss of flesh. His weight was 9 stones 3 pounds. There were emaciation and dilatation of the stomach There was no tumour. An operation for the stricture of the pylorus (pyloroplasty) was performed (a bone bobbin being used) On Sept. 19th, 1898, the patient's medical attendant writes: "For some time little improvement; stomach now works well. Looks better than I have ever seen him." He was well in February, 1901, and had gained his normal weight.

---

[6] Loc. cit.

CASE 15.—The patient was a woman, aged 46 years, who was seen on March 18th, 1897. She had stricture with active ulceration at the pylorus. She had had gastralgia for several years which was relieved by food. In November, 1894, she vomited a dark fluid; since then she had had frequent vomiting, the longest interval being two or three weeks. There was pain in the stomach, accompanied by a hard lump and often followed by vomiting. There was great loss of flesh and strength. Operation was as follows. Pyloroplasty for contraction and thickening of the pylorus; the passage only admitted a No. 2 catheter. Good recovery ensued and she was well in 1899. There was considerable gain in weight.

CASE 16.—The patient was a man, aged 39 years, who was seen on May 24th, 1897. A letter, dated May 13th, 1897, says: "During the last 18 months I have suffered much pain which has caused me to be bedfast for two, three, or four weeks at a time, and it has required another month or more for me to gain strength enough to move about." 18 months ago he had epigastric pain several hours after food, which was relieved by vomiting. Since then his health had never been good; three and a half months ago he had a similar attack, very severe, with collapse. The vomit contained blood. 14 days ago he had another severe attack. His normal weight was 10 stones 10 pounds; it was now 9 stones 3½ pounds. His stomach had been "weak" since childhood. There was marked dilatation. There was no tumour. On operating it was found that there was a deep ulcer at the pylorus, the extreme stricture barely admitting the ordinary director. Pyloroplasty was performed, a bone bobbin being used. There was complete recovery from operation and the patient rapidly regained normal weight. A letter dated Feb. 16th, 1898, says: "I thought you would like to know that I am able to attend business as usual, and have done so without interruption since July 19th, 1897."

CASE 17.—The patient was a woman, aged 46 years, who was seen on July 12th, 1897. She was said to have had ulcer of the stomach 20 years ago. Since then she had been subject to attacks of pain from half an hour to two hours after food and sometimes continuous pain. For three or four months she had been vomiting three times a day and had lost a stone in weight in that time. She was leading the life of an invalid and for a long period was under medical treatment without benefit. There were dilatation of the stomach, visible peristalsis, and tenderness over the stomach, especially at the pylorus. No tumour could be felt. On operating it was found that the stomach was much dilated; there was thickening at the pylorus. Pyloroplasty was performed, a bone bobbin being used. Good recovery ensued. On Jan. 8th, 1898, the patient weighed 11 stones, a gain of over two stones.

CASE 18.—The patient was a man, aged 23 years, who was seen on July 27th, 1897. He had had vomiting and loss of flesh for two years. He once weighed 10 stones, but was now seven stones in weight. Dieting and lavage gave only temporary relief. There were emaciation, pallor, and dilatation of the stomach. There was no tumour. On operating it was found that the pylorus was much contracted; there was great hypertrophy; the walls were more than one-third of an inch thick. Pyloroplasty was performed, a bone bobbin being used. Good recovery ensued. On Dec. 12th, 1897, the patient's weight was 9 stones 13 pounds and he was well.

CASE 19.—The patient was a man, aged 52 years. He had suffered from indigestion for two years. This, however, had not interfered much with his general health till the previous Christmas, when the indigestion was accompanied every second day by acute pain and vomiting, coming on about two hours after food. The vomited matter was in large quantity, offensive, and sour, and at times coffee-ground in character. From this time the patient became extremely weak and pale and rapidly lost flesh to the extent of one and a half stones in five weeks. He had pain on pressure over the pylorus, but no distinct tumour was felt. There was marked dilatation of the stomach, and during the attacks of pain it could be felt to harden under the hand. On April 8th, 1895, the abdomen was opened by an incision in the middle line above the umbilicus, exposing the pylorus, which formed a distinct tumour adherent to, and under cover of, the liver, and which, after being freed from adhesions to surrounding structures, was found to be tightly strictured, so as only to admit the passage of a No. 12 catheter, the mucous membrane being extensively ulcerated and the walls thick and almost cartilaginous. The stricture was incised longitudinally and sutured transversely over a bone bobbin by a double row of sutures. The stomach was much dilated and atonic. Though the pyloric tumour gave rise at the moment to a suspicion of cancer there was no evidence of growth and the glands were not affected. On Oct. 30th, 1896, he called to report himself, looking robust and well. He had gained three stones in weight since his operation.

Gastroplasty is an operation that I have successfully employed in a number of cases of chronic ulcer leading to hour-glass stomach. It consists in making a longitudinal incision through the strictured part of the stomach and bringing the edges of the wound together transversely, thus obliterating the stricture. A convenient method of performing the operation is by the use of a large decalcified bone bobbin as described in the cases appended. If the strictured part of the stomach be actively ulcerating the ulcer must be excised at the same time, otherwise subsequent contraction may occur; or possibly the ulcer, already chronic, may persist and lead to a continuance of the symptoms; in such a case, if excision be impracticable, gastro-enterostomy must be performed, or if the pylorus be free from disease the operation of gastro-gastrostomy may be done in order to short-circuit the constriction. I have operated on 13 cases of hour-glass stomach due to chronic ulcer, with 12 recoveries. The following are good examples.

CASE 20.—The patient, a woman, aged 29 years, gave a four years' history of ulceration of the stomach, with vomiting of blood on one occasion, and the presence of melæna several times. As the pain was always easier when the patient was lying on the back an ulcer on the anterior surface of the stomach was diagnosed. This was confirmed at the operation, as the anterior wall of the stomach was so puckered that the cavity was divided into two, which were connected by a narrow channel, which was laid open by a free longitudinal incision in which was laid a large bone bobbin, the wound being then brought together transversely over it, thus leaving a channel of nearly two inches between the two cavities. The patient went home within the month and has completely recovered her health and strength.

CASE 21.—A man, aged 44 years, was admitted with well-marked dilatation of the stomach and a history of 20 years' gastric trouble. The constriction in this case was two and a half inches from the pylorus, the cavity between the stricture and the pylorus being very much smaller than the proximal one. The treatment was by gastroplasty over a large bone bobbin. Recovery was delayed by an attack of pleurisy, but the patient was now quite well and had gained rapidly in weight.

CASE 22. *Double hour-glass contraction of the stomach; gastroplasty and gastrolysis.*—The patient was a woman, aged 30 years. There had been attacks of pain and vomiting for 15 years. The pain began at the left side and passed to the epigastrium and through to the left subscapular region. There had been severe hæmatemesis 10 years before. Occasionally, both before and since, the vomit had been streaked with blood, which was sometimes "coffee-ground," but it had contained no large quantity of blood for eight years. The patient vomited large quantities at times and had lost flesh steadily for the last five years. There were dilatation of the stomach and peristalsis. No tumour could be felt but the pylorus was felt to harden from time to time. Operation was performed on June 6th, 1899, at a surgical home in Leeds. Double hour-glass contraction was discovered. One-third of the distance from the cardiac extremity adhesions caused a marked diminution of calibre, and two inches from the pylorus a contraction only admitting the tip of the little finger was found. The adhesions were divided and gastroplasty was performed, the wound being sutured over a large bone bobbin. The after-history was as follows. The patient made an uninterrupted recovery and in two months she had gained two stones in weight.

CASE 23. *Extreme hour-glass contraction; gastroplasty.*—The patient was a woman, aged 48 years. She had had constant indigestion and flatulence for 20 years, with a feeling of pulsation and tenderness at the epigastrium. There had been free hæmatemesis two years before and vomiting occasionally since, but lately the patient had ceased to take much solid food. She had noticed slime and blood in the motions, possibly due to constipation, which was extreme. There had been great loss of flesh. No tumour was present, but there were tenderness in the epigastrium and a well marked splash on succussion. Operation was performed on July 28th, 1899. There was extreme contraction one third of the way from the pylorus which just admitted the tip of the little finger. Gastroplasty was performed, a large bone bobbin being used. With regard to the after-history, the patient made a good recovery from the operation and the indigestion was relieved. There was an increase in weight of about a stone and improvement in the general health, but the stomach remained dilated and she continued anæmic and weak. This was at first thought to be due to bleeding from piles, but after they had been ligatured the weakness still continued, and, although there was no vomiting, flatulency and discomfort after meals with loss of appetite led to a suspicion of recurrence of disease in the stomach, which on being distended with CO_2 reached three inches below the umbilicus and on being washed out after a test meal showed impaired motility. On Jan. 24th, 1901, the abdomen was opened again through a median incision above the umbilicus when marked dilatation of the stomach was seen with contraction and some thickening over the pylorus, but where the hour glass contraction had been operated on 18 months previously it was interesting to note that neither scarring nor contraction were seen and it would have been impossible to tell by naked-eye appearances that anything had been done. A posterior gastro enterostomy was performed, a bone bobbin being employed. Recovery was uninterrupted and before the patient left the home at the end of the month she was taking ordinary food with relish and without any discomfort. She had then gained several pounds in weight.

Adhesions of the stomach to adjoining organs are so common in chronic stomach ulceration that gastrolysis or the detaching or otherwise treating bands and short adhesions to adjoining viscera or to the abdominal wall is performed in by far the greater number of cases. Such adhesions are frequently the only remnants of ulcers that have healed; at other times they have been left by perforation of the stomach wall by an ulcer, from the direful consequences of which they have saved the patient. In many cases they give rise to symptoms resembling ulcer, though the adhesions may be due to causes such as gall-stones outside the stomach itself; in such cases the operation of gastrolysis may be entirely curative. I have performed gastrolysis in 56 cases, all of which have recovered. The following case is given as an example.

CASE 24. *Gastrolysis for adhesions caused by chronic gastric ulcer.*—The patient was a woman, aged 42 years. 22 years ago she had symptoms of ulcer of the stomach; since then she had suffered from attacks of vomiting every week or two and from pain after food During the last three years the symptoms were more marked. Under medical treatment, with rest in bed, there was no improvement. The vomit was large in quantity and fermenting, sometimes containing blood. There was loss of weight to the extent of three stones. There was great tenderness over the stomach, especially to the left. The stomach was dilated, reaching below the umbilicus and well over to the right. At the operation on the anterior surface of the stomach the scar of an old ulcer was visible. The lesser curvature of the stomach was closely adherent to the liver. The pyloric extremity and the first part of the duodenum were attached to the gall-bladder and the cystic duct. The adhesions were separated and omentum interposed between the pylorus and gall-bladder. With regard to the after history, there was perfect recovery. On March 7th, 1900, the patient could eat anything without discomfort and was rapidly putting on flesh. She had gained 20 pounds since her operation. In March, 1901, she was quite well and had gained over two stones in weight.

Many other examples could be given where the benefits derived from operation have been quite as great.

Pylorodiosis, by which name is understood the operation of stretching the pyloric sphincter, either by means of the fingers invaginating the stomach wall (when it is known as "Hahn's operation") or by digital or instrumental stretching after having made an opening into the stomach (when it is known as "Loreta's operation") is a method of little practical value in the treatment of ulcer, and in some of the cases where I performed the operation, though the immediate results were good, relapses subsequently occurred. If performed by invagination without opening the stomach cavity it is an operation unattended by risk. It may possibly be of service in simple spasm of the pylorus, but I have not much faith in its effects being lasting.

It would be easy to give from my own experience examples of operations for all the complications of gastric ulcer that I have mentioned. I will, however, now only mention the results of my experience in operations for simple diseases of the stomach out of over 200 operations that I have performed. In 56 cases I have performed gastrolysis for the separation of adhesions which were producing disabling conditions, all the patients recovering. In 13 cases I have operated for hour-glass stomach due to ulcer, 12 of the patients recovering and being now well. In six cases I have operated for hæmatemesis, with five recoveries; in four cases for fistula due to chronic ulcer, all the patients recovering. Of the 18 cases in which I have performed pyloroplasty 16 have recovered, the two deaths being in the earlier cases, one being due to perforation in the second week after operation Of the posterior gastro-enterostomies previously referred to for simple diseases of the stomach, in 40 cases there were two deaths, both due to accidental causes, one being pneumonia in a phthisical patient Of the anterior gastro-enterostomies, including cases operated on 10 years ago, in 19 cases there were four deaths, one from an accident at the time of separation of a Murphy's button, one from shock in a patient very exhausted at the time of operation (Senn's plates being used), one from perforation of an ulcer on the twelfth day, when apparently convalescent, and one from peritonitis extending from the abdominal wound. Of the two gastroplications both recovered. Of the three cases of pylorodiosis all recovered. In eight operations for perforating gastric ulcer there were two deaths directly following on operation in cases treated when peritonitis was general. Of the six cases in which I directly excised a gastric ulcer or ulcers after opening the stomach by gastrotomy all recovered. Of one case of gastrotomy for the removal of foreign bodies and one for perforating wound of the abdomen with hæmatemesis both patients recovered. It will be seen that out of 177 operations for simple diseases of the stomach 165 patients recovered, or 93 2 per cent.

In the course of my paper reference has been made to a method which I have been systematically pursuing since 1891, not only in stomach operations, but in nearly all the operations which involved the making of an anastomotic opening between the hollow viscera—I mean the method of suture over a decalcified bone bobbin. I have adopted it in a very large number of cases and in a great variety of operations, and as a result of this extensive experience I am more than ever convinced that it is a reliable procedure which I can thoroughly recommend to others. It is more easily demonstrated than described, but it is really very simple and only involves two continuous sutures, one of chromicised catgut to unite the mucous margins of the two openings and one of celluloid thread to unite the serous surfaces about a quarter of an inch away from the new opening Pagenstecher's thread or spun celluloid has replaced silk in my practice, it being stronger, easily sterilised by boiling, and less absorbent. The bobbin, which is made for me by Messrs. Down Brothers of London in various sizes, from the small one required for cholecystenterostomy or for the union of the small viscera of children, to the large one employed for gastroplasty or for the end-to-end union of large intestine in the adult, is nothing more than a cylinder of decalcified bone with raised ends, which is placed in the new anastomotic opening, around which the sutures are applied.

The advantages claimed for the method are: (1) that it secures the opening being of the exact size intended and that there is no possibility of the passage being made too small by the drawing up of the sutures before the knots are tightened; (2) that it secures an immediately patent channel between the two anastomosed viscera; (3) that the bobbin protects for from 24 to 48 hours the new line of union from pressure and from the irritation of the visceral contents; (4) that it facilitates the application of the sutures and so adds to the expedition of union by sutures; (5) that no foreign material is left in the alimentary canal which may irritate or cause subsequent trouble, for the bobbin rapidly dissolves in the alimentary juices; and (6) that the method has now been proved by ample experience to be rapid, easy, efficient, and safe For stomach operations it is used in gastro enterostomy, in pyloroplasty, in gastroplasty, and in pylorectomy or partial gastrectomy, and in the latter operation it is unnecessary to use more than two continuous sutures for the whole operation.

In adopting the method it is convenient to begin with the serous suture, which is applied around the posterior half of the circle; the needle still threaded is then laid aside till the final stage; the openings into the viscera are then made and any redundant mucous membrane cut away; the mucous suture is now applied, uniting the posterior half of the circle; the bone bobbin is now inserted and the mucous suture continued around the anterior half-circle until it reaches the point where the mucous stitch was begun and where the loose end will be found, these two ends are then tied firmly; the serous suture previously laid aside is now picked up and continued around the anterior half-circle until the loose end of the celluloid thread is reached, when the two ends are tied firmly. The two hollow viscera are now united by a hollow cylinder of decalcified bone surrounded by two continuous threads, one uniting the mucous margins and one the serous surfaces, about a quarter or one-third of an inch away from the anastomotic opening.

Leeds.

ANALYSES OF
STOOLS AND URINE FROM EPILEPTIC PATIENTS UNDER TREATMENT WITH "BROMINOL" COMPARED WITH SIMILAR SPECIMENS FROM PATIENTS UNDER POTASSIUM BROMIDE.

BY W. HARRISON MARTINDALE, PH.D.

[THE instructive investigations by Dr. W. Harrison Martindale described in the following paper were undertaken at my suggestion. I had been unable to obtain the same satisfactory results from the administration of Merck's bromipin, or the equivalent English preparation, as have been described by German observers, and it seemed desirable to ascertain whether any considerable amount of the oil-compound escaped absorption. It will be seen that the results give no support to the suspicion, and they confirm the statements made regarding the presence of bromine in the urine after the administration of the compound. The clinical observations on its influence are not yet sufficiently numerous or decisive to justify their publication. Dr. Martindale's results, however, are complete and may wisely be made known.—W. R. GOWERS]

"Brominol" is the name given to an additive compound of bromine and sesame oil (the oil from seeds of *Sesamum orientale*, one of the cotton-seed oil group), containing 33⅓ per cent. of the halogen in chemical combination The dose of the preparation is from 10 to 60 grains (from 0 65 to 4 0 grammes) which is approximately equal to from five to 30 grains of potassium bromide. The compound forms a thick yellow oil, odourless and of oily taste. Its specific gravity is 1 0125. A 10 per cent. preparation is also made and a quarter-ounce dose of this equals approximately 20 grains of potassium bromide.

CHEMISTRY OF HALOGENISED FATS AND OILS.

The compound is an example of a halogenised fat and as these brominised and iodised bodies have been used both externally (an iodised oil has been recommended for inunction in rheumatism) and more recently have been administered internally, by rectal injection, hypodermically, and rubbed into the skin (e g., bromipin and iodipin, Merck) I give a short description of the chemistry of halogenised fats and oils before proceeding to the question of the relative absorption of alkaline bromides and ingestion of brominol. The reason for selecting sesame oil as a vehicle for the halogen is that it is tasteless, that it is easily digested, and that it is a cheap oil of commerce. Similar compounds may be prepared with other fats and oils, and the resulting products—e g., brominised cacao butter and lard—differ little in physical characters from the fats from which they are prepared.

Fats and oils are mixtures of the neutral glycerides of acids of the higher homologues of the paraffin, of acids of the oleic (acrylic) and linoleic (propiolic or sorbinic) series. The acids of the first-mentioned and their glycerides are saturated bodies having in their molecule a single linkage throughout, and therefore do not possess the power of adding halogen. The bodies of the next (the oleic) series are derived from hydrocarbons of the ethylene group, unsaturated, and by reason of their double linkage add bromine or iodine; the double linkage is broken with the result that di-halogen-substitution products of the corresponding acids of the paraffin series are formed, e.g.:—

$$C^{18}H^{34}O^{2} + 2\ Br = C^{18}H^{34}Br^{2}O^{2}$$

Oleic acid. Di-bromo-stearic acid.

Finally, the acids of the linoleic type and their glycerides are derived from hydrocarbons of the acetylene series, contain either a triple or two double linkages and are capable of adding either two or four atoms of halogen, e g.:—

$$C^{18}H^{32}O^{2} + 4\ Br = C^{18}H^{32}Br^{4}O^{2}$$

Linoleic acid. Tetra bromo-stearic acid.

It is thus evident that in choosing an oil for internal administration of a considerable quantity of bromine or iodine in chemical combination one containing a large proportion of acids of the paraffin series (e g., palmitic or stearic acids) is not suitable, and, on the other hand, the fats of the linoleic group, though absorbing a considerable quantity of halogen, are unsuited (e.g , linseed oil) by their unpalatability or are not general articles of commerce. In the case of iodine absorptions it is necessary to use some aid to induce addition, as when employed alone the interaction is slow. For this purpose the compound iodine-chloride or iodine in an alcoholic solution of mercuric chloride yield good results. Mills found that sesame oil would absorb 47 4 per cent. of bromine, while sweet almond oil would absorb 53 7 per cent., cotton-seed oil 50 per cent, raw linseed oil 76 per cent., boiled linseed oil 102 4 per cent., and cod-liver oil from 81·6 to 86 7 per cent. Olive oil assimilated 54 per cent. of bromine against the theoretical amount (54·3 per cent.) required for the compound $C^{3}H^{5}(C^{18}H^{33}Br^{2}O^{2})^{3}$.—(Allen.) Figures thus obtained are analytical data and in halogenising on the large scale allowances have to be made in order to ensure complete combination. In the case of iodine these percentages constitute the "iodine number" of the fat or oil and form a valuable aid to the identification and detection of substitutes in the olive oil of commerce.

PREPARATION OF BROMINOL.

Brominol is prepared by the action of bromine-monochloride in alcoholic solution on sesame oil or by the action of ethereal solution of bromine itself on ethereal solution of sesame oil. Considerable heat is produced unless due precautions in cooling are taken. The bromine fumes necessitate working in the open air or in a draught-chamber. In the manufacture small quantities of acrolein and hydrobromic acid are produced. It is therefore necessary thoroughly to wash the brominised oil with repeated quantities of warm alcohol to remove these impurities Finally, the product is dried to remove the alcohol by heating in vacuo and the strength in bromine is determined by a Carius's analysis if direct combination has been employed or by other suitable method if the bromine-chlorine compound has been used. The bromine is in slight excess to commence with and after its determination the product is adjusted by the addition of sesame oil so as to contain 33⅓ per cent.

Chloroform may also be used in the place of ether for solution. Mixtures producing bromine-chloride—e g., potassium bromide, sodium nitrite, and hydrochloric acid, or a mixture of potassium bromide with a chlorate—are also mentioned in Merck's specification of the German patent "bromipin" as being utilised for brominising, but these bodies are obviously unnecessary complications.

ANALYTICAL DATA.

At the suggestion of Sir William R. Gowers I have undertaken investigations with a view to determining whether this halogenised oil, brominol, passes through the system unchanged or whether it is absorbed. According to Merck's Report the compound "bromipin" is acted upon by the pancreatic secretion and the bile, split up, and is absorbed in the intestine.

Dr. H. Douglas Singer, house physician at the National Hospital for the Paralysed and Epileptic, Queen square, has kindly forwarded me specimens of stools and urine for examination in order that a comparison might be made between relative proportions of bromine in these excreta from epileptic patients under treatment with brominol and with potassium bromide respectively. The stools of patients under brominol were carefully desiccated on the water bath and the dried substance was powdered and passed through a fine sieve The resulting powder was then extracted with ether of a specific gravity of 0·720 in a Soxhlet apparatus for a day or more until the liquid passed over colourless The ether was distilled off and the residue in the flask was carefully dried and weighed This was examined for bromine by fusing with dried sodium carbonate or with a fusing mixture of potassium nitrate and sodium carbonate The fused mass thus obtained was dissolved in nitric acid and examined for bromide with silver nitrate, and with carbon disulphide and chlorine water The residue in the Soxhlet thimble was then examined for bromine (in the form of bromide) by fusing in a similar way and testing as above

The stools from patients under potassium bromide would not be expected to contain bromine in an ether soluble (fat) form in the fæces, but it seemed desirable to dry and extract these also with ether alongside the above in order to confirm the results and compare the amount of fats obtained in the two treatments respectively

The bulk of the urine from patients under both treatments was evaporated as nearly as possible to dryness on a water bath, and small quantities of the residue were fused with sodium carbonate and potassium nitrate, and preliminary qualitative examinations for bromine conducted as before The quantitative determination of the halogen presented some difficulty, owing to the natural presence of a considerable quantity of chlorides A method was initially adopted of treating the fuse obtained from a weighed quantity of the residue with strong sulphuric acid in a separator, adding chloroform and excess of potassium permanganate, and shaking out the liberated bromine It is important that the chloroform should already be present when the bromine is liberated by the permanganate This chloroformic solution was added to an excess of alcoholic potassium iodide, and the bromine in turn liberated an equivalent of iodine which was finally titrated with $\frac{N}{10}$ thiosulphate From the amount of thiosulphate used it is an easy matter to calculate the amount of bromine in the quantity of urine residue taken for analysis, and thus by multiplication to arrive at the bromine content in the volume of urine—e g, in the amount voided in 24 hours

Another method employed was to precipitate the halogens as silver salts from the nitric acid solution of a weighed quantity of fuse The silver salts (bromide and chloride) were weighed and heated in a stream of chlorine From the loss in weight due to the displacement of the bromine by chlorine the proportion of bromine present may be found and calculated into the equivalent contained in the urine passed in 24 hours The results are tabulated

Specimens	Nature of material.	Case under—	Weight of material in grammes.	Weight of residue on drying	Residue per cent.	Extractive with ether	Bromine in residue (after ether extraction in the case of stools)
A	Stool	Brominol 33⅓ per cent. one drachm sextis horis (four times in 24 hours).	161	43 grammes.	26·7	8·9 per cent. of original material contained decided traces of bromine.	Traces.
B	Urine.		1120	19 grammes	1·7	—	Analysis 1: 0·6 gramme of bromine from total material = 1·8 grammes (27 grains approximately), 33⅓ per cent of bromine. Analysis 2: 0·7 gramme of bromine from entire material = 2·1 grammes (31 grains approximately), 33⅓ per cent. of brominol.
C	Stool.	Potassium bromide, 30 grains ter die	85·05	30 grammes.	35·3	6·4 per cent. of original material Contained no bromine.	*Nil*
D	Urine		1120	28·9 grammes	2·6	—	Analysis 1: 1·12 grammes of bromine from total material = 1·67 grammes (25 grains approximately) of potassium bromide. Analysis 2: 1·1 grammes of bromine from total material = 1·64 grammes (25 grains approximately) of potassium bromide.

Having by me at the conclusion of these analyses small quantities of the Specimens B and D, which I had reserved as *corpus delicti*, I decided for final confirmation to examine these also for bromine content The results were as follows 100 grammes of Specimen B, evaporated to dryness with potassium nitrate, incinerated and the bromine estimated by the chlorine method, gave 0·161 gramme AgBr = 0·064 gramme of bromine, or 0·72 gramme of bromine, from 1120 grammes of sample 140 grammes of Specimen D, treated similarly, yielded 0·288 gramme AgBr = 0·122 gramme of bromine, or 0·98 gramme of bromine, from 1120 grammes of the specimen These figures, though not as accurate as the data in the table, nevertheless confirmed the latter

NOTES ON THE CASES UNDER TREATMENT

A Stool from patient, a female, aged 32 years, under treatment with brominol (33⅓ per cent) one drachm every six hours Time of passing stool, April 4th, 10 30 A M; time of previous stool, April 2nd, 10 A M

B Urine from the same patient under brominol treatment, collected during the 24 hours from March 21st, at 7 A M, to March 22nd, at 7 A M

C Stool from a male patient, aged 24 years, under treatment with potassium bromide (30 grains ter in die) The stool was passed on March 22nd at 8 30 A M The bowels had been previously opened on March 21st, at 8 30 A M This patient had before (up to March 11th) been under treatment with brominol

D Urine from the same patient as last specimen, collected during the 24 hours between March 21st, at 8 30 A M, and March 22nd, at 8 30 A M

By a glance at the table of analyses it will be seen that we are able to account in the urine, in both the brominol and potassium bromide treatments, for somewhat more than one-quarter of the quantity of bromine administered in the day. Taking Analysis 2 of Specimen B into account it is seen that three eighths of the total quantity of bromine administered passes off in the urine (one drachm of 33⅓ per cent brominol four times daily = 80 grains of bromine) In the brominol treatment small quantities of unaltered brominol and bromides are passed per rectum Other portions may pass off by the skin or lungs

The exact manner in which assimilation takes place is not easy to decide In an experimental research by Moore and Parker[1] it is concluded that "in the property of acting as a solvent for substances insoluble in water bile has its main if not its only function, both in excretion and absorption this clearly explains the part played by bile in fat absorption" These workers' results, amongst other valuable and interesting data, throw light "on the relative functions of the pancreatic juice and bile in fat digestion and absorption. The enzyme of the pancreatic juice splits up the neutral fats, forming free fatty acids, which are largely converted into soaps by the alkali present, while the bile gives solubility to the fatty acids and soaps so produced"

The digestion and absorption of brominol may be explained by the principles indicated by these authorities—namely, that the pancreatic enzyme splits up the compound, forming free fatty acids, which are to a large extent saponified by the alkali present, and the bromine is by the same agency converted into alkaline bromide. The bile then causes solution of this saponified mass of soap, fatty acid, and alkaline bromide, the latter by its easy solubility passing off in the urine. Considering the close combination of the bromine atoms in the molecules of the fatty acids and the general stability of the compound brominol it is remarkable from a chemical aspect that the halogen is absorbed to the extent to which analyses of the urine show to be the case. It may be put forward that the work to be done by the bile and tissues in converting the bromine into this soluble form is probably advantageous in producing its necessary effect in nerve trouble.

---

[1] Communicated to the Proceedings of the Royal Society, vol lxviii, No. 443, by Professor Schäfer

In conclusion, I consider that these halogenised fats deserve a more extended trial because I think that it may be argued that in some cases this ingestion may prove of benefit where the alkaline bromide by reason of its great solubility would pass off rapidly without producing its full action.

New Cavendish-street, W.

TWO CASES OF CARCINOMA TREATED WITH CACODYLATE OF SODA.

BY EDWARD MARTEN PAYNE, M.B., C.M. ABERD.

THE idea of treating cancer with arsenic is not new. There was a story told of a German countess who, being stricken with the complaint, was so horrified that she determined to forestall a lingering and painful death by taking a large dose of arsenic which, however, instead of killing the countess, cured the cancer.

CASE 1.—On Jan. 14th, 1900, I was consulted by a patient, aged about 45 years, relative to irregular and rather profuse discharges of blood from the vagina. She attributed the occurrence to the "change of life," and as she objected to a physical examination I prescribed a mixture of ergot and sulphuric acid, which stopped the floodings for the time being. On April 17th I was consulted again and this time I made a vaginal examination but found no very definite signs except a certain amount of purulent discharge, from which the patient said she had suffered for a long time. The ergot and sulphuric acid mixture was again prescribed and the patient was better in two days. On June 13th I find she had another bottle of the mixture, but she did not consult me again until August 14th. She would not be examined, so I prescribed the old mixture and she went away to the seaside. On Oct 5th I received an urgent message to go to see her at her own house. She had had a very severe attack of hæmorrhage while she was in the country and a medical man who had been called in had told her that she had cancer of the womb and had not long to live. This time I insisted upon making an examination and I found that the cervix was ulcerated and that there was fixation of the uterus. As the patient and her friends were extremely unwilling to believe that the disease was of a malignant nature I, after a good deal of difficulty and delay, persuaded them to let me call in a well-known gynæcologist who confirmed the diagnosis and who said that operative methods would be useless. This was on Nov. 29th. For the sake of doing something I had already been treating the case with Fowler's solution, and on Dec. 16th I commenced hypodermic injections of cacodylate of soda. On the first day I injected two centigrammes, on the next four centigrammes, and on the next five centigrammes, and I kept up the last named dose daily until Jan. 16th, 1901, when I increased the daily dose up to 7·5 centigrammes, which was the maximum dose that I employed in this case. The injections were continued daily, with occasional intermissions, until Feb 25th, when the patient got so tired of the needle that at her earnest request I let her have a mixture containing the drug in doses of 2·5 centigrammes which she took three times a day until March 14th, when for some reason or other she suddenly refused to go on with the treatment.

As to the results, unfortunately I could never get my patient to let me make another vaginal examination, so I was obliged to form my conclusions on other data. As to the general state of the patient's health she and all her friends agreed that there was a great improvement. She left her bed and took walks out of doors, and even travelled all the way from the distant suburb where she lived to look at the shops in Regent-street. Her colour improved. She wore close-fitting dresses which had been made for her a year ago and they fitted her exactly still. She gained weight, as much as two pounds in three weeks. The hæmorrhage ceased and the white discharge diminished. When the patient was at her work she had complained much of constipation which I believed to be due to pressure of the tumour on the rectum. This condition also became very much improved. In short, the patient herself got so much better that she finally declared that she could never have had cancer, and this was her excuse for giving up the treatment.

CASE 2.—The next case I shall describe is one of an old man, aged about 70 years. On August 2nd, 1900, he complained of a sore mouth and tongue. The tongue was a little ulcerated. There were several jagged old teeth and stumps which were thought to be the offenders, the tongue was a little swollen generally, but there was no localised swelling. A mouth-wash was supplied and after some persuasion two teeth were extracted on Sept. 10th and another one on Nov. 24th. There were no more complaints about the mouth until March 14th, 1901, when the patient told me that he felt as if he had a hole in the middle of the tongue. On examination it was found that there was a deep depression in the middle of the upper surface of the organ, and immediately beneath the depression was a hard substance of about the size of a large filbert. I suspected carcinoma, so I made known to the friends of the patient my apprehension and suggested that a specialist should be consulted. They did not care to have a specialist, but my partner, Dr. Whitehall Cooke, kindly came and after examining the patient he expressed his conviction that the case was one of carcinoma. We both agreed that considering the patient's age an operation was not advisable. On March 17th I commenced hypodermic injections of cacodylate of soda, beginning with a small dose and gradually increasing it to 7·5 centigrammes. From the first the patient said that he felt much better in himself and at the present time, after about six weeks' treatment, I am sure the swelling under the tongue is no larger; indeed, I think that it is less and that the surface of the tongue is less retracted. There is less soreness of the gums but it is not always absent. On one occasion I noticed that some of the lymphatic glands in the neck were swollen but the swelling subsided in a few days. On the outer surface of the inferior maxillary bone about the region of the left incisive fossa a swelling appeared about the time the treatment was commenced; this also has subsided somewhat.

I have given the above notes for what they may be worth, for although I fear that I cannot claim that the results I have recorded are of a very decisive nature I am myself strongly inclined to the opinion that cacodylate of soda, even if it cannot claim to be a *cure* for the cancer, is at least a very valuable palliative. It certainly seems to arrest the progress of the disease and it improves the patient's general condition, and I am of opinion that it should at least be tried in those cases where early operative methods are out of the question.

I have a theory of my own as to how arsenic acts in cases of cancer. It is well known that arsenic, which is so much prescribed in "skin diseases," has, if pushed too far, a deleterious effect on that organ. An excellent series of cases bearing on this subject is given by Mr. J. Hutchinson in the *Polyclinic*.[1] Amongst these several cases are recited in which the continuous use of the drug has been said to produce cancer and cancerous ulcers, or, at any rate, growths and ulcers, which appeared to be morphologically identical with cancer when examined under the microscope. Now in view of the theory which has of late years been revived and is at the present time in growing favour with pathologists—viz, that cancer is due to the irritation of the epithelial cells by a specific micro-organism—may we not fairly question whether, after all, these growths and ulcers which have been attributed to the effect of arsenic are really pathologically identical with the growths and ulcers known as cancers? If cancer be due to the irritation of the epithelial cells by a specific organism then these ulcers and growths either are not cancerous or if they are they are not due to the arsenic but occur coincidently only with its administration, unless, indeed, it be maintained that the arsenic acts as a secondary or exciting cause by which the dormant energies of the latent micro-organism are stimulated to action. Now there are so many of these cases quoted that it does not seem probable that the appearance of these cancers is purely coincidental, although it might happen that the cancer was the ultimate manifestation of an abnormal condition of the epithelial cells which at first showed itself in the shape of the psoriasis or whatever it was that was the primary object of treatment. The theory that the arsenic stimulates the dormant organisms into a state of activity seems too far-fetched to be accepted without further evidence, so we are thrown back upon one or the other of the following suppositions—viz., that the growths and ulcers following excessive doses of arsenic are *not* truly cancerous but are pathologically distinct although morphologically similar; or that cancer is a growth having a certain morphological structure pathologically due to some epithelial irritant and that amongst such irritants arsenic is one In any case it seems certain that arsenic has a specific action on the epithelial cells, at first beneficial, ultimately destructive. It also seems to be a plausible theory that on coming in contact with the epithelial cells in a person suffering from cancer its deleterious effects would be resisted more vigorously by the normal physiological cells, while pathological cancerous cells would be the first to be overcome and destroyed.

Cricklewood, N.W.

ACUTE COLITIS IN CHILDREN.[1]

BY EDMUND CAUTLEY, M.D. CANTAB., &c.,

PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN, ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL.

IT is a remarkable fact that the occurrence of acute colitis, or ileo colitis, in epidemic form is almost unknown, or at any rate unrecorded, in England Even in America, where diarrhœal affections in children are more common and more severe during the hot season than in England, the disease does not appear to have attracted attention as an epidemic. A small but very definite outbreak has recently come under my observation and is well worthy of publication. Six out of 30 children were affected and of these patients four died. Four of them came under my care, two of whom died. Three out of 13 adult women were attacked less severely and recovered. The first case I saw in consultation with Mr. D. Boyd Keown who kindly agreed to transfer the child to the Belgrave Hospital for Children for treatment and has since supplied me with the following particulars of the epidemic.

Habitation.—All the cases broke out in certain London barracks, in rooms opening on to a common staircase. On this particular staircase there are four floors with four rooms on each floor. 13 families, consisting of 13 women and 30 children, occupied these 16 rooms, three of the larger families having two rooms apiece. On the third floor lived three women with two, two, and five children respectively. The first case broke out on this floor on June 20th, 1900, and the second on June 30th. Two out of the family of five children were affected and both died (Case 1 and Case 2). On the second floor lived three women, one of whom had four children. No case occurred on this floor. On the first floor lived three women, one of whom had four children, another had five children, while the third had none The last cases broke out here at the beginning of August. The mother of five and two of her children were attacked and one of the children died. On the ground floor lived four women with three, three, two, and no children respectively. The family of the mother and two children were all affected, the first on July 14th, and of these the younger child died. One of the women with three children was attacked, but not severely, and her children escaped. Thus the epidemic started on the top floor, then broke out on the ground floor, and finally on the first floor.

Etiology.—As far as could be ascertained by personal inspection no fault could be found with the water-supply, the lavatory accommodation, or the drainage inside the building. Just outside the entrance a pipe, carrying the rain-water from the roof, opened into a gully from which the grating had been removed. This gully was frequently full of stagnant offensive water, and in one instance (Case 3) the child had been noticed putting her hands in the water and then in her mouth. It must, however, be pointed out that other children living on adjacent staircases had access to this water and that the outbreak was limited to the one staircase. The milk-supply for the families affected came from two different milkmen. The food-supplies were bought outside the barracks. A very careful investigation by Mr Keown and myself did not enable us to ascertain what the source of infection had been. Although the cases occurred during the hot months of the year the weather was colder than usual at the time.

The following are short details of the four cases which came under my charge.

CASE 1.—A girl, aged five years, was admitted into the Belgrave Hospital for Children on June 28th, 1900, and she died on July 1st. On June 22nd the family had some fried mackerel of which the child partook. Vomiting and diarrhœa began at 4 A.M next day and persisted in spite of treatment. On admission the child was very ill and cold and wasted; the temperature was normal and the pulse was 140. Nothing abnormal was found on physical examination. The abdomen was lax and empty and it was nowhere tender. Vomiting continued. The diarrhœa was profuse as regards frequency, 20 stools being passed on the 29th and 14 on the next day. The stools were small, sometimes not more than a tablespoonful at a time, green, containing mucus and blood, and very offensive. There did not appear to be any pain or tenesmus, though there was a history indicating a certain degree of tenesmus The child rapidly got weaker and she died from exhaustion at 2 25 A M. on July 1st. The temperature reached 101° F a few hours before death.

CASE 2.—A boy, aged three years, was admitted to the hospital on July 1st, 1900, and he died on the 8th. The patient was brother of the first child and they had slept in the same bed. He was quite well until the afternoon of June 30th and was a fine, strong, well-nourished boy. Illness began with abdominal pain, vomiting, and diarrhœa. On admission his temperature was 103° F., the pulse being 144 and the respirations 36 Nothing abnormal was found on physical examination. Possibly the abdomen was a little distended, but there was no tenderness. The course and symptoms were the same as in the first case. The stools numbered from 11 to 20 in the 24 hours; they were small and green, containing bright red blood, mucus, and a little fæcal matter, and were very offensive. Vomiting was troublesome and persistent. On the day before death he brought up some blood. He took food badly, was very restless, and he died from exhaustion. No other cases occurred in this family. Temperatures were taken every four hours, the highest and lowest readings Fahrenheit for each day being as follows:—July 1st: highest 103°; lowest, 98·8°. July 2nd: highest, 101·4°; lowest, 98°. July 3rd: highest, 100·8°; lowest, 98·8°. July 4th: highest, 100·8°; lowest, 98·2°. July 5th: highest, 101°; lowest, 98·2°. July 6th: highest, 100·2°; lowest, 97·4°. July 7th: highest, 99·8°; lowest, 97·2°.

CASE 3—A female infant, aged two years, was admitted into the hospital on July 18th, 1900, and was discharged cured on August 27th. She was the elder of two, the other being a baby at the breast It could not be ascertained that the illness was due to any deleterious article of diet, but on July 13th, the day preceding the onset, the child was noticed putting her hands into the dirty water previously mentioned and then into her mouth. On the 14th she was languid and had diarrhœa In the evening she vomited after taking medicine and she had a little colic. Next day the vomiting was continuous and the diarrhœa was worse, with a large amount of blood in the stools. The hæmorrhage was severe on the following day and then it diminished, more mucus being passed. On admission she had a temperature of 101° F., was well-nourished, and presented a moderate degree of abdominal distension, without pain or tenderness. The fever lasted for a fortnight; it was rarely up to 100° F. Vomiting ceased on the 20th. The diarrhœa persisted for a fortnight, the stools becoming less frequent and more fæcal. They were never as numerous as in the first two cases, 12 being the maximum number in the 24 hours. At first they presented the usual characteristics and were very green. No blood was seen after the 31st and no mucus after a few more days. The stools were unformed and offensive for a further 10 days and after that they became normal. At first the child was very ill, lethargic, and fed badly, but she improved steadily with the cessation of the diarrhœa Otitis media occurred as a complication. Soon after this child was taken ill and before she was transferred to the hospital the infant, aged three months and entirely breast-fed, was similarly attacked. She died after two weeks' illness, characterised by pyrexia and diarrhœa, the stools being green and containing blood and slime. After the baby the mother was attacked and she passed blood in her stools for four days Another adult woman living on this floor was also affected but less severely. She had three children who escaped.

---

[1] A paper read before the Medical Society of London on May 13th, 1901.

Case 4.—A male child, age three years, was admitted into the hospital on August 11th and was discharged cured on Sept. 17th, 1900. He was one of five children living on the first floor. This proved to be the mildest case of the series. The patient was taken ill on the 8th, and when admitted he did not seem very ill. His tongue was clean; the temperature was 100° F., and the pulse was 130. The stools were offensive and they contained blood and mucus. The vomiting and characteristic stools persisted for a week, but the stools never exceeded four in the 24 hours. Pyrexia was slight for four days. After a week recovery was steady and uneventful though slow. A brother of this patient was similarly affected, his illness beginning a week before the patient was attacked. He was admitted into another hospital and there he died. The mother was also severely attacked and was in bed for a week.

Morbid anatomy.—In the first case it was found that the whole of the large intestine, from the cæcum to the anus, was enormously thickened, so much so as to form an almost rigid tube. The thickening involved the whole wall, but it especially affected the mucous membrane. On the surface of the latter were some superficial minute abrasions, hardly sufficient to call ulcers, and small hæmorrhages. The last few inches of the ileum were acutely inflamed, but little if at all thickened. There was another small patch of inflammation in the ileum higher up. The mesenteric glands were swollen and one bronchial gland was caseous. Nothing else of importance was found. The second case presented somewhat similar appearances. The acutely inflammatory condition of the whole of the large intestine was present as well as considerable thickening, but there was not the enormous thickening found in the first case. For quite two feet the lower end of the ileum continuous with the cæcum was acutely inflamed, and a patch of similar inflammation about six inches long was found in the ileum higher up. On the surface of the inflamed mucous membranes were small hæmorrhages and superficial abrasions, but no definite ulceration. In both of these cases the total duration of the illness was almost identical, but in the first the effect on the large intestine was much more severe than it was in the second In both the main stress of the attack fell on the large intestine, the amount of inflammation in the ileum being in comparison of quite minor importance.

Nomenclature.—A certain amount of criticism may be directed to the name which I have given to this disease. That it deserves a special name must, I think, be conceded in view of the characteristic symptoms, course, and morbid anatomy. It must, however, be pointed out that cases of this description are generally included in that group of diseases described under the names zymotic diarrhœa, inflammatory diarrhœa, enteritis, entero-colitis, ileo colitis, and dysentery or dysenteric diarrhœa. If one name be taken to include the whole of this group of diarrhœal diseases that of "ileo-colitis" is apparently the most appropriate, for in the large majority of the cases there is present some degree of inflammation of the ileum. It appears to me that the time has come to differentiate these affections In ileo-colitis, as described in the text-books, it is usually stated that in only about half the cases is the ileum involved. Surely, then, many of these cases can be more appropriately classified under the name "colitis." The morbid anatomy of the two fatal cases showed distinctly that the main stress of the pathological process fell upon the large intestine. In fact, in the first case the effect on the large intestine was so striking as to suggest the name of "acute proliferative colitis" for the disease. The second case would come more satisfactorily under the heading of "acute catarrhal colitis." On the whole, I am of the opinion that this latter name is the more suitable one for the cases in this small outbreak. There is more than a superficial change in the epithelium such as occurs in ordinary gastro enteric infection. According to the nature and extent of the change a further differentiation can be made. Thus acute catarrhal colitis may occur with or without ulceration; or a follicular colitis may occur, and further a pseudo-membranous form has been described.

General description.—There is very little doubt that the cause of the disease is some form of microbial infection or toxæmia, almost certainly the former. The actual variety of micro-organism responsible has not been definitely ascertained either in these cases or in others which have been investigated. In Case 2 Dr. F. W. Andrewes found the bacillus enteritidis sporogenes and the bacillus coli communis, but could not definitely ascribe the disease to either organism. Streptococci were found by Booker in the deeper lesions in some cases which occurred in America. In a few others, which were no doubt true dysentery, the amœba coli was found by Cahn. Although the disease is most common in hot weather, it may occur at any season of the year. Sometimes it is secondary to infectious diseases such as measles, diphtheria, and some forms of broncho pneumonia. Ulceration of the colon may also result from enteric fever and dysentery. and is occasionally due to tuberculous or malignant disease. The disease under consideration is most frequent in infants under two years of age; in fact, a certain amount of catarrhal or follicular colitis is not uncommon in fatal cases of inflammatory diarrhœa in infants at this period of life. It is noteworthy that in the present outbreak only one infant under two years of age—viz., a breast-fed infant three months old—was affected; that the age of the other children varied from two to five years; and that three adults were attacked. Proportionately, the percentage of adults attacked was as great as that of the children. Probably the primary source of the infection was some article of food or drink. In some instances it appears likely that the disease was acquired by direct infection from a previous case, perhaps from a lack of absolute cleanliness while attending to the invalid. Thus, the second case may have been acquired by infection from the first through sleeping in the same bed, which was undoubtedly contaminated by the fæcal discharges. Also, the mother in the third case was attacked subsequently to her children, and, seeing that the stools of the child first ill were frequent and offensive and that she was nursed for some days by the mother, direct infection is a likely explanation. Moreover, the young child was entirely breast-fed and did not have even water in addition to the mother's milk.

Symptomatology and course—In each case the onset was sudden, with vomiting, diarrhœa, and pyrexia. Vomiting is a most pronounced symptom, being frequent and persistent, varying in severity in different cases. It is not due to any affection of the stomach and is most probably dependent on reflex irritation, though possibly it is caused by a toxin acting on the nervous centres. Anorexia is complete and, like the vomiting, is independent of gastric conditions. The tongue in one of the milder cases remained clean throughout, but in the others it was somewhat furred and it tended to become dry and brown in the centre. The stools are very frequent, small, green, very offensive, and contain mucus and bright red blood and little or no fæcal matter. Although frequent the diarrhœa is not profuse, the stools being sometimes only about half an ounce in amount. There is no marked tenesmus. It was noted in the first case as present but as being slight, and was absent in the other three cases. The abdomen may be retracted and empty or it may be moderately distended. In no instance was any tenderness discoverable along the course of the colon. The facial aspect is of the abdominal type—sunken eyes, pallor, and an anxious look. Restlessness is a marked symptom and there is very considerable nervous prostration, quite out of proportion to the amount of diarrhœa and very suggestive of a general toxæmia. The character of the pyrexia is well illustrated by the temperature record of Case 2. In the fatal cases the vomiting, diarrhœa, restlessness, and fever persist in spite of treatment and death results from the rapidly increasing asthenia, which seems to be due largely to the effect of the poison on the nervous system and by no means to the severity of the diarrhœa. In a more favourable case the tongue, if furred, rapidly cleans; the blood disappears from the stools, the mucus next lessens, and the amount of fæcal matter increases, the stools becoming less frequent. The stools retain their offensive odour for some days after the diarrhœa ceases and even when the motions are solid. With the cessation of the diarrhœa the pyrexia subsides.

Prognosis.—The prognosis is bad in the acute cases. Although five out of six of the children were over two years of age, no less than three of them died. The indications on which I lay most stress as being of serious import are vomiting, uncontrolled by drugs and diet, and restlessness. The frequency of the stools and the persistence of blood and mucus in them are also indicative of the severity of the attacks.

Treatment.—The treatment must be directed to maintaining the strength of the patient and stopping the diarrhœa and vomiting. Warmth and rest in bed are essential. Diet is all-important, for in face of the complete anorexia and vomiting it is extremely difficult to get the child to retain sufficient food. Thin arrowroot made with water is retained fairly well. Other foods of value are albumin-water, meat juice, peptonised milk, milk diluted with a thin farinaceous fluid, and unsweetened condensed milk. In the worst cases nothing is retained long, the vomiting being due to reflex irritation or toxæmia and not to any gastric cause or the nature of the food. Stimulants are essential and may be used freely. Brandy is the best. Of drugs I found hydrochlorate of cocaine (in doses of one-hundredth of a grain) the most useful to stop the vomiting, and salicylate of bismuth in large doses for the diarrhœa. Other drugs were tried, but the above gave the best results. Urotropine was given with a view to disinfecting the alimentary canal but it exerted no influence on the offensive character of the stools. Opium by the mouth did not seem to be beneficial, and enemata of starch and opium were only of slight value. Rectal irrigation was tried in one case unsuccessfully. Theoretically irrigation of the large intestine would be beneficial by washing out mucus, micro-organisms, and other deleterious matters present. Practically it is very difficult to carry out efficiently in children and is strongly objected to. In view of the fact that the pathological process is more than a superficial one irrigation is unlikely to be of any great benefit. If used, a weak solution of boric acid is the best. Silver nitrate should not be employed.

PATHOLOGICAL REPORT ON CASE 2, BY DR. F. W. ANDREWES.

The only organisms isolated were the bacillus enteritidis sporogenes and the bacillus coli communis. The former was obtained from the colon in anaerobic milk culture after heating to 80° C. for 10 minutes. It was virulent on a guinea-pig. The latter came out in almost pure culture in aerobic cultures on gelatin and agar-agar. Its virulence was not tested, but various chemical tests were applied and they showed that it was the ordinary bacillus coli communis and not Gärtner's bacillus enteritidis.

Microscopical examination.—The contents of the colon, stained with methylene blue and Gram's method, show a vast number of micro-organisms of very various kinds of which short bacilli, resembling bacillus coli communis, are the most abundant. Very few streptococci can be recognised. Sections of the colon show a high degree of congestion. The mucous membrane is ulcerated away in many places, exposing the submucosa but not the muscular coat. At such places especially there is an infiltration with round cells, but this does not involve the muscular coat. The epithelium of the colon is desquamated in many places, including Lieberkühn's crypts. The submucosa, on the whole, shows very little infiltration, except where actually laid bare by ulceration. Sections stained for micro-organisms show plenty on the surface of the mucous membrane and in the crypts, but they do not extend deeply into the mucous membrane. They are chiefly bacilli resembling the bacillus coli communis.

Upper Brook-street, W.

PRESENTATIONS TO MEDICAL MEN.—Mr A. B. Pugh, for some time house surgeon of the Huntingdon County Hospital, on his leaving the neighbourhood has been the recipient of a travelling clock, subscribed for by 150 people of Godmanchester and Huntingdon, in recognition of his kind attention and medical skill.—At a meeting held at the Westminster Palace Hotel on May 15th Mr. E. L. Jacob, M.R.C.S. Eng., who has recently resigned the office of medical officer of health of the Surrey United Sanitary District, after 27 years' active service, was presented with a silver tea and coffee service by the gentlemen with whom his official work brought him into close association. The county treasurer, Mr. Francis H. Beaumont, of Buckland Court, Betchworth, presided. The meeting was well attended and comprised a large number of professional brethren and officials.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF RUPTURED INFERIOR VENA CAVA: VITALITY AFTER SEVERE INJURY.

By ADRIAN CADDY, M.B. LOND.,
HOUSE PHYSICIAN, ROYAL FREE HOSPITAL.

A BOY, aged eight years, was brought to the casualty room of the Royal Free Hospital on Feb. 28th, 1901, with a history of being run over by a dustcart. The first thing we noticed was a large lacerated wound on the outer side of the right knee-joint, with a tear in the capsule of the joint. The left knee-joint had a worse wound about three inches square on the inner side completely denuding the bone and exposing the semilunar cartilage which was quite loose between the femur and tibia. The boy, when first seen, did not appear to be much hurt and sat up and talked freely about a pain in his left side. On examining his thorax the majority of his ribs seemed to be fractured. He then gradually got worse, becoming very pale, with a pulse of 140 and very thirsty. He gradually became unconscious, and finally died two and a half hours after admission. At the necropsy extensive bruising was found all over the front of the thorax. The left ventricle of the heart had a large bruise on its anterior surface. There was a pint of blood in the left pleural cavity, there was a laceration of the base of the lung two inches long, and there were seven fractured ribs on the left side. On the right side six ribs were fractured and there were four ounces of blood in the right pleural cavity. In the abdomen the inferior vena cava was discovered completely torn across; there was no rupture of the liver or injury to the diaphragm, the tear in the vein being between the liver and diaphragm. There were 12 ounces of blood in the peritoneal cavity and a slight bruise of the transverse colon. All the other organs were uninjured and healthy.

The interest of this case lies in the fact of the boy's power of living after such extensive injuries for two and a half hours, excluding the time required to bring him to hospital (20 minutes), the injuries including the rupture of the largest systemic vein of the body, laceration of the lung, and bruising of the left ventricle of the heart.

A RARE CAUSE OF SUDDEN DEATH.

BY G. HERBERT METCALFE, M.R.C.S. ENG., L.R.C.P. LOND.

I WAS sent for on the evening of Feb. 16th, 1901, to see a girl, aged 13 years. On my arrival I found that she was dead, apparently asphyxiated. I was given the following history. The patient had been quite well for the last year with the exception of a slight cough after food or on exertion for the last three days. Five minutes before my arrival she started to run upstairs sucking an orange, but suddenly returned to the room gasping for breath and fell back dead. Three years previously I had attended her for right-sided phthisis, but about a year ago I considered her cured. The only cause of death that occurred to me was the impaction of a piece of orange in the trachea. A post-mortem examination was made 24 hours after death, at which I was kindly assisted by Miss Margaret S. Sharp, M.B. Lond. The right pleura was firmly adherent throughout. On opening the trachea it was found blocked by pieces of caseous gland. On the right side, half an inch above the bifurcation, was a round hole with smooth edges admitting a No. 12 catheter. This communicated with a sac containing caseous gland similar to that found in the trachea. There was an old fibroid tuberculous lesion at the root of the right lung almost completely healed. The cause of death was evidently the sudden blocking of the trachea by the rupture into it of a caseous gland. This case shows the importance of a post-mortem examination. I should be glad to hear of any similar cases that may have been reported.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

KING'S COLLEGE HOSPITAL.

A CASE OF GASTROSTOMY FOR MALIGNANT DISEASE OF THE STOMACH.

(Under the care of Mr. W. ROSE.)

THE coexistence of the cysts of the kidney with the malignant disease of the stomach in the following case appears to have been a mere coincidence. Gastrostomy for carcinoma of the stomach itself is a rare operation and can only be required when the new growth is confined to the cardiac half of the viscus, for when the malignant growth affects more than half of the stomach a jejunostomy is preferable. For the notes of the case we are indebted to Mr. R. Sturgeon Cocke, house surgeon.

A woman, aged 69 years, was admitted into King's College Hospital under the care of Mr. Rose on Nov. 24th, 1900, with the following history. She had suffered from dyspepsia for years, but five months before admission she began to experience difficulty in swallowing. The dysphagia gradually increased so that on admission she was quite unable to swallow solids and only a small quantity of liquid, most of her attempts at deglutition being unsuccessful and immediately followed by regurgitation, suggesting an obstruction at the lower end of the œsophagus. Moreover, chronic constipation had existed for a like period, and she had lost weight to the extent of three or four stones, and there was marked cachexia. Careful auscultation failed to detect anything in the nature of an aneurysm. The urine was normal in every respect. As it was found impossible to pass an œsophageal bougie in the ordinary way the patient was anæsthetised and several sizes were introduced in succession, but in every instance the bougie was arrested at a point about 12 inches from the teeth. It was therefore obvious that the only operative treatment feasible was gastrostomy, since there was everything to indicate the existence of a malignant growth.

On Dec. 3rd the patient was again anæsthetised with a view to the operation of gastrostomy, and whilst the abdomen was being purified in the usual manner a rounded swelling of about the size of a fœtal head was seen and felt at the junction of the umbilical and left lumbar regions. The swelling was fairly moveable and its limits could be easily defined on account of the lax and thin condition of the abdominal wall. The abdomen was opened by a vertical incision five inches long, about one inch to the left of the median line, commencing two inches below the costal margin, the fibres of the rectus being separated by the finger. On introducing the hand into the peritoneal cavity the swelling was found to be cystic and connected with the lower end of the left kidney. On attempting to separate it the kidney substance was torn, leading to troublesome hæmorrhage, and the cyst opened, allowing of the escape of a considerable quantity of pale straw-coloured inodorous fluid; as no connexion could be found with the pelvis of the kidney it was probably serous in nature. Further examination of the organ revealed the existence of a similar cyst connected with its upper end; the wall was thin and easily gave way. The kidney was next drawn out of the wound and freed from its surroundings, and after the ureter and vessels had been severally tied it was removed.

In order to examine the condition of the stomach the incision was enlarged upwards for an inch and a mass, probably carcinomatous, was felt which at first appeared so extensive as almost to preclude any operative measures. On further examination, however, it was found that the pyloric end and lower portion of the great curvature were free and that the disease was mainly limited to the cardiac extremity. A cone-shaped portion near the pylorus was drawn into the upper part of the wound and its base was stitched to the parietal peritoneum and posterior layer of the sheath of the rectus. The sides of the cone were stitched to the rectus muscle and its apex to the skin through which it protruded for about half an inch. The lower portion of the abdominal wound was closed in the usual way after a counter-opening in the loin had been made for drainage. Finally, a small opening was made in the stomach at the apex of the cone and a piece of rubber tubing of the size of a No. 10 catheter was stitched in so that about two inches of it protruded into the viscus and three or four inches were outside. Four ounces of milk together with an ounce of brandy were at once introduced through the tube. Antiseptic dressings were applied in such a way that the tube could be reached for feeding purposes without disturbing the wound.

The patient suffered a great deal of pain for the first few days after the operation, but this was relieved by morphia. The food was well retained and there was not a sign of regurgitation. A little fluid given by the mouth was also swallowed and this relieved the dryness of the tongue and feeling of thirst. The urine was diminished for a few days and contained a trace of albumin, and the patient suffered from retention necessitating the use of a catheter. Diarrhœa set in on the third day with slight melæna, lasting four days. The temperature never rose above the normal. The drainage-tube from the loin was taken out on the fourth day and the stitches were removed from the abdominal wound at the end of a week. The subsequent course of the case has been as satisfactory as could be expected. The pain was considerably relieved for a time. The patient gained flesh and there was no difficulty in administering nourishment, since no regurgitation occurred through the opening and no irritation of the surrounding skin.

On March 10th, 1901, the patient's condition was as follows. She weighed 5 stones 10 pounds. The temperature was normal and the pulse was 68, full and regular. She was being fed by the stomach-tube every five hours, 16 ounces being administered at each feed. Benger's food was chiefly used and once a day a soup made of spinach and potato was given. The pain was variable, but seemed to have got worse lately, extending from the seat of the disease to the left shoulder, and requiring occasional doses of morphia. The bowels were constipated, though for a short time after the operation there was some diarrhœa. The constipation was overcome by glycerine enemata, since the administration of any aperient by the stomach brought on painful tenesmus. The general condition improved for some time, but the cachectic condition was becoming more marked. After this date the patient's condition steadily deteriorated and she died on April 3rd. Unfortunately no post-mortem examination was permitted.

Remarks by Mr. ROSE.—The most interesting feature in this case is the coexistence of a cystic kidney with malignant disease of the cardiac orifice of the stomach. From the excellent progress made by the patient after the operation it was evident that the left kidney had been for some time functionally useless, and that the relief of pressure consequent on its removal acted beneficially rather than otherwise. It was clearly in accordance with the principles of surgery to ascertain the nature of this abdominal growth, as until this was done it was impossible to say how far its presence would neutralise any efforts directed to the stomach. Had, for instance, this growth involved and obstructed the intestinal tract lower down the performance of gastrostomy would have been useless. As it was, the patient's life was prolonged for about four months, during which time the artificial opening acted most satisfactorily. There was no regurgitation and hence no irritation of the skin around. I should mention that the method I employed was a modification of Frank's operation, suggested and practised by my colleague, Mr. A. Carless. In it the apex of the cone of gastric wall is fixed in the upper angle of the incision, and the rectus muscle after being detached from its sheath is sutured together around it, thus constituting a very efficient sphincter.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A CASE OF TYPHOID FEVER WITH SUTURE OF THE PERFORATED BOWEL; RECOVERY.

(Under the care of Dr. H. MALET and Dr. E. DEANESLY.)

THE diagnosis of perforation of a typhoid ulcer is frequently very difficult, but sudden severe pain in the right iliac region occurring in the course of an attack of typhoid fever is practically sufficient to justify the diagnosis. Whether recovery ever follows in these cases without operation is doubtful. Occasionally patients have recovered after a diagnosis of perforation of a typhoid ulcer has been made, although no operation has been done, but naturally a doubt has always existed as to the correctness of the diagnosis, for only in fatal cases has it been possible to verify it. For all practical purposes it may be said that laparotomy offers the only chance of recovery, and it should be performed as soon as the diagnosis is made unless the patient is moribund. For the notes of the case we are indebted to Dr. H. F. Parker, house physician.

A youth, aged 17 years, was on Feb. 18th admitted into the Wolverhampton and Staffordshire General Hospital under the care of Dr. Malet. The patient, who was suffering from typhoid fever, first felt ill on the 13th when he had some shivering, backache, and abdominal pain. On admission the temperature ranged from 100° to 103° F., the pulse varied from 68 to 80, and the tongue was dry and furred. There was no bronchitis; there was slight distension of the abdomen but no pain, the spleen was not palpable, and there were no rose-spots. Widal's reaction was dubious on the 19th but was subsequently well marked. The bowels were moved on the 19th after the administration of 2 drachms of castor oil. No aperient was given after this date. His condition steadily improved and the morning temperature had become normal on the 27th, the fifteenth day from the first symptom of his illness. On that day at 3.30 A.M. he was awakened by sudden violent abdominal pain which caused him to roll about in agony. Two hours later he vomited. The abdomen was then found to move very slightly with respiration and to be tender but not distended. The pain was not localised but was referred to the whole of the abdomen. The temperature was 98 4° and the pulse was 96. The liver dulness was normal. Turpentine stupes were applied; pain soon subsided and the general condition greatly improved. Flatus was passed, the pulse fell from 96 to 84, and the abdomen moved more freely. The temperature, however, rose to 102 8°. At 10.30 A.M., seven hours after the first onset of pain, the patient was seen by Dr. Deanesly who decided to operate at once.

The operation was performed in the ward without moving the patient from his bed. Chloroform was administered and the skin of the abdomen was thoroughly cleansed. On opening the abdomen by a three-inch oblique incision in the right iliac region turbid yellow fluid was at once found among the coils of small intestine and welling up from the pelvis. The second coil of small intestine which was brought out for inspection immediately disclosed a small perforation in the centre of a circular ulcer, the outline of which was visible through the coats of the bowel. The ulcer was situated opposite to the mesenteric attachment and was of about the size of a shilling. The perforation was in its centre, and fluid similar to that in the peritoneal cavity was seen escaping from it together with bubbles of gas. No other perforation was seen, but the possibility of the existence of more than one perforation, although borne in mind, was not thought to justify a prolonged search. The whole ulcer was invaginated by a complete transverse folding of the intestine and fixed in this position by a double row of continuous sero-muscular sutures of fine silk passing through healthy tissue at some distance from the margin of the ulcer. The peritoneum was then cleansed thoroughly by pieces of moist gauze passed among the adjoining coils and also down to the bottom of the recto-vesical pouch. The total quantity of extravasated fluid was estimated at seven or eight ounces. No drain was inserted. The peritoneum and transversalis fascia were sutured with a fine continuous suture of silk and the rest of the wound was brought together with silkworm-gut sutures.

The operation, which lasted about one hour, was borne without the slightest sign of shock, the pulse at the finish being 84 and of good volume. One tenth of a grain of morphia was injected as soon as consciousness returned and the patient was soon asleep. There was no vomiting after the operation and flatus was passed the same evening. After the first 24 hours his condition never gave rise to anxiety and the temperature scarcely rose above normal. The wound, however, which was unavoidably contaminated by the extravasated fluid, suppurated on the fourth day and the stitches had to be removed. The wound then granulated readily and healed quite soundly, the peritoneal suture not having required removal. The bowels were moved on March 3rd by an enema and solid food was allowed on the 16th. The patient got up on the 31st and was discharged in good health on April 6th.

Remarks by DR. DEANESLY.—When I first saw the patient the most remarkable thing about him was the absence of anything in his aspect or pulse to suggest a serious abdominal lesion, and this in spite of the fact that no opiate had been administered. The only signs that I could detect were a slight but distinct deficiency of abdominal respiration and a little tenderness in the right iliac fossa. Nevertheless, the history of the attack was so unmistakeable and the house physician's account of it was so accurate and circumstantial that I did not hesitate to operate. I do not know whether a lateral incision is usually adopted for this purpose, but from the common situation of the majority of ulcers occurring in typhoid fever an incision in the neighbourhood of the cæcum appears to me to be preferable to a median section. At any rate, I was fortunate in finding the perforated ulcer with great ease. Invagination of the whole ulcer is the most obvious method of closing the perforation as it is impossible to suture the rotten tissues over the ulcer itself. This cannot be done by means of a longitudinal fold without dangerously narrowing the lumen of the bowel, but by a transverse folding of the bowel an ulcer of any size can be invaginated without producing more than a moveable internal spur something like an exaggerated valvula connivens. I have adopted this method for dealing with a localised gangrenous patch of bowel in a case of strangulated hernia with a perfect result.

The question of drainage or no drainage is always a difficult one in such cases and must be decided in each case on general principles. In this case the short duration and small amount of extravasation decided me to trust to the peritoneum to deal with all that was left after a careful cleansing. In this expectation I was not deceived, but it is significant of the varying capacity of different tissues for dealing with the same infective agent that the parietal wound suppurated while the peritoneal infection was arrested.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Acute Colitis in Children.—Rheumatic Chorea, its Varieties and their Treatment.

A MEETING of this society was held on May 13th, Mr. JOHN H. MORGAN, the President, being in the chair.

Dr. EDMUND CAUTLEY read a paper on Acute Colitis in Children which is published *in extenso* at p. 1463 of our present issue.—Dr. F. DE HAVILLAND HALL remarked on the frequency of "summer diarrhœa," so-called, and expressed the opinion that the term had much too wide an application. The different varieties of pathological condition to which the term was applied were not, he thought, sufficiently differentiated. There were many indications in Dr Cautley's cases which supported the notion that the colitis was of toxæmic origin, such, for instance, as the absence of any local pain or tenderness.—Mr. F. C. WALLIS remarked on the selection of the colon by the disease which seemed to be strictly localised to this structure. What was the reason for this special proclivity? He suggested that this was very probably due to the differences in the chemical composition of the contents of the large bowel as compared with that of the small intestine. The contents of the small intestine had actively digestive properties, and in fæcal fistulæ communicating with the small bowel great trouble was experienced in protecting the skin around the wound. This was not so in fistulæ connected with the large bowel. Perhaps the absence of digestive substances from the colon allowed bacteria to obtain a footing in the latter.—Dr. A. F. VOELCKER, referring to his experience in the dead house, remarked that most cases of colitis proved at dilata- necropsy to be part of a generalised gastro-ente the hæmor- would like to ask Dr Cautley what were th ollected records which he concluded that the vomiting in condition seemed independent of any stomach lesion? He average age was 48 ask whether Dr. Cautley had tried crea was equally common in the treatment of these cases? H was 36 years. There employed these remedies in simila of calcified pericardium considerable advantage and there cardiac signs at all in a indication for the employment of diagnosis even of adherent

Dr. CAUTLEY, in replying, remarked that the children died in this disease from general infection. This was consistent with the absence of local signs. Although there was general involvement of the colon there was a notable absence of local signs. The order in which his cases had developed the disease was first the child, then the infant, who caught the disease from the child, and then the mother. Why the disease should be limited to the colon he could not say. Mr. Wallis's explanation was feasible up to a certain point, but in his belief the main reason was because the intestinal contents stayed longer in the colon. The best treatment, if seen early, was free purgation to start with. Irrigation of the bowel had been tried but it only did partial good. Operative treatment was of very doubtful use. He did not use creasote. Post-mortem signs had been his chief guide to treatment. He did not think that intestinal antiseptics would be beneficial. His favourite remedy was salicylate of bismuth, with cocaine to stop the vomiting. The evidence on which he concluded that the vomiting was probably of toxæmic or reflex origin was the cleanness of the tongue and the absence of catarrh from the stomach and small intestines.

Dr. LEONARD GUTHRIE read a paper entitled Remarks on Rheumatic Chorea: its Varieties and their Treatment. He regarded ordinary or Sydenham's chorea as a rheumatic manifestation and not as a disease in itself. "Fright" cases were not in a different category, for fright was only another name for shock. The results of shock were the same, whether produced by injury, by chill and exposure, or by emotion. Shock from any cause lowered vitality and favoured the action of the rheumatic diplococcus. When chorea ensued there was doubtless some peculiar instability or weakness of the nervous system as well. Chorea was divided for convenience of description into two main varieties—sthenic or explosive and asthenic or pseudo-paralytic—each of which was subdivided into severe and mild. Severe sthenic cases were characterised by spontaneous, uncontrollable, conflicting movements, which were increased on attempted voluntary action, and also when the patient was under observation. The milder sub-varieties of sthenic chorea were: (1) cases in which spontaneous movements ceased during rest but were excited by voluntary actions and by observation of the patients; (2) cases in which spontaneous movements could be controlled by an effort of will, but the effect was to produce rigidity of the limbs and extreme incoördination in attempted voluntary actions; and (3) cases of residual chorea in which the symptoms continued, but the complaint seemed cured, for spontaneous movements ceased and voluntary actions could be performed without ataxy and rigidity when the child made an effort of will. The duration of severe sthenic cases seldom exceeded two or three weeks. Sometimes one or other of the sub-varieties then made its appearance, but more frequently severe sthenic cases became equally severely asthenic in character. Sometimes mixed cases in which both types prevailed were met with. In severe asthenic chorea all choreic movements ceased and the patient seemed paralysed from head to foot. Rapid emaciation was the rule. Mania or dementia was not uncommon and complete mutism lasting many weeks sometimes occurred. In milder cases movements were also absent and the patient seemed paralysed in one or more limbs. Mild cases of sthenic and asthenic chorea at times became severe and the severely asthenic seldom became severely sthenic in type. The treatment of severe sthenic cases consisted in absolute rest in bed, protection from injury, and in some cases restraint of movements by splints and bandages. Chloral hydrate and bromides were the best remedies. Other sedatives were useful. Severe asthenic cases required rest in bed, abundant diet, stimulants and tonics, massage, and occasionally galvanism. The methods used in milder sthenic cases were (1) suggestion; (2) suggestion with passive movements; (3) suggestion with voluntary movements under guidance; (4) voluntary movements and exercises without guidance; and (5) incoördina-[illegible] treated on Frankel's system used in locomotor ataxy [illegible]ses and various toys and games to aid precision in [illegible]. Treatment by suggestion and encouragement of [illegible]re also useful in cases of asthenic [illegible]dinary doses did good in most [illegible] heroic doses of the drug [illegible]justifiable, and dangerous.—[illegible]ning arsenic as it was at [illegible]hat effect Dr. Guthrie had obtained by starting with large doses and continuing it only for a limited time. The treatment suggested by Dr. Guthrie was more applicable to the rich than to the poor. The methods of treatment by physical exercises would doubtless be very useful if skilled assistance was at hand. His experience of treating children by "suggestion" was not very satisfactory.—Dr. CHARLES CHAPMAN asked whether such large doses (six to eight ounces) of brandy were not as detrimental to children in other ways, even if they did good for the disease.—Dr. ALEXANDER MORISON asked whether Dr. Guthrie had noticed any relation between the type of case and the incidence of endocarditis. He thought that those curious, fatuous, aphonic cases were relatively exempt from endocarditis. He quite endorsed the views against large doses of arsenic if continued for long, but given in a more moderate manner it seemed to have a special effect on the disease.—Dr. VOELCKER remarked that treatment must depend largely upon the pathology of the affection. Dr. Guthrie seemed to regard these cases of chorea as due to the action of a rheumatic poison on the nerve cells producing over-action. His (Dr. Voelcker's) view was that it rather removed the inhibition of the cerebral influence. If that were so the education of these children to build with bricks and play with toys was not rational. Rest seemed to him to be a more rational method so as to allow of recuperation. Residual chorea might, however, be treated by Kindergarten games and physical exercises. He had not a great belief in large doses of arsenic, but small doses seemed to influence the disease.—Dr. GUTHRIE, in reply, said that in his experience large doses of arsenic seemed to make children sick—a fortunate circumstance, for it saved them from its toxic effects. He had found that it was more difficult to get skilled assistance in private practice than in hospital. Treatment by "suggestion" and exercises must be confined to cases in which the acute stages had been got over. The use of large doses of stimulants no doubt wanted watching. As to the occurrence of endocarditis, he thought that it was less frequent in asthenic than in sthenic cases. He felt sure that chorea degenerated (or developed) into a "habit," and gradually evolved exercises were very useful in preventing the perpetration of the disorderly movements of chorea in the form of habit spasms or tricks.

Annual Oration.—Conversazione.

A meeting of this society was held on May 20th, Mr. JOHN H. MORGAN, the President, being in the chair.

Mr. F. RICHARDSON CROSS (Bristol) delivered an oration on Some Landmarks in the Progress of Medical Science. After referring to the important part played by time in the affairs of men, the orator alluded to the close of the Victorian era, the longest, most prosperous, and the most remarkable period in the history of the British nation, paying also a rare tribute to the influence of Her late Majesty. For 63 years her influence had been ceaselessly directed to uplift and purify the life of the nation. She was the living symbol of the unity of the empire and would continue to live in the undying reverence and affection of her former subjects. It was said that the Egyptians and Babylonians exposed their sick in public so that any passer-by might give his aid by former personal experience and those relieved were required to go to the temples and there record their symptoms and their cures. Before Hippocrates, early Egyptian practice was in the hands of the priest physicians. The sick attended at the temple where they were relegated to some one specially acquainted with their particular malady. The Jews probably learned their medicine from the Egyptians; their guiding principle was cleanliness, and the regulations of Moses for the public health were of more than passing interest. Greece was the motherland of rational medicine, and from the time of Hippocrates to that of Harvey it was always the medicine of the Greeks that alone commanded attention, whether it emanated from the schools of Alexandria, Rome, Bagdad, Salerno, or Paris. Homer (B.C. 1250) told of the Thessalian chieftain and blameless physician Æsculapius, and of his sons Machaon and Podalirius who acted as surgeons in the Trojan war. Pythagoras (B.C. 582) raised a school of more philosophic medicine, and the services of medical men were recognised in Greece as of high value for the welfare of the State. Many towns kept a physician for the public service and Herodotus mentions that the physician Democedes (B.C. 520), a pupil of Pythagoras, was chosen public medical officer at Ægina with a salary of a talent (£240) per annum, an income far in excess of that received by an Athenian

Ambassador of those days. He afterwards went to Athens in the same capacity and then to Samos where he received a salary of two talents. It was the master mind of Hippocrates (B.C. 460) that gathered up what was best and gave to medicine an impress of his own, teaching that careful observation and recorded facts were essential for wisdom in medical science. He denied that disease had a supernatural origin: "from God comes one disease as well as another, but nothing happens except in conformity with nature." His knowledge of diagnosis and treatment was marvellous when it was remembered how superficial was his acquaintance with anatomy, for the Greeks religiously guarded the bodies of the dead. Plato (B.C. 427) and Aristotle (B.C. 384) were next referred to. The former seemed to have but a poor opinion of medical men, but Aristotle, a pupil of Plato, was a member of a medical family and educated as a physician. He founded a school of anatomy at Alexandria where anatomy was first studied by dissection. His plans and methods of classification were copied 2000 years afterwards by Cuvier. For centuries the Alexandrian school was the focus of the intellectual life of the world. Hérophilus and Erasistratus (about B.C. 300), Philoxemus and Ammonius were among the workers there. The orator then passed briefly to consider the various schools of teaching which sprung up—the Rational or Dogmatic school of Hippocrates, the Empirics, the Methodists, and the Eclectics. In the second century before Christ Marcus Portius Cato, the censor who strove to stem the tide of Greek luxury, gave some useful surgical rules in his "De Re Rustica." The first physician of eminence who practised in Rome was a Greek, Asclepiades (128 B.C.), a friend of Cicero. He left behind him a number of worthless imitators who desired to be judged by the luxury they displayed rather than their knowledge, and a few more capable pupils who developed the methodic system. In Rome medical men seemed to have had but a poor social position and most of them were foreigners or freedmen. The calling was considered unworthy of a Roman citizen, at any rate, until the first century of the Christian era. In the Roman period the physician (*medicus clinicus*) and the surgeon (*chirurgicus*) seemed to have been clearly distinguished. Celsus was the greatest man associated with Roman surgery, but it was doubtful if he ever operated, or, indeed, if he was a medical man at all. Galen (A.D. 131 to 201) was a Greek but went to Rome. Subsequent Greek and Roman authors were mainly compilers from his writings. After his time the practice of dissection was apparently given up for centuries. Amidst the general disregard of learning in Europe during the Middle Ages the practice of the healing art was maintained chiefly among the religious orders, where it was much interwoven with augury, divination, cheiromancy, astrology, and alchemy, excepting perhaps among the Benedictines. In their hands the practice of physic became so lucrative that an ordinance of Pope Innocent III. debarred the clergy from undertaking surgical operations in 1215. This threw the practice of surgery into the hands of the barbers and bone-setters who practised it mechanically and without any special training or anatomical knowledge. About 1423 an effort was made to form a conjoint faculty of medicine and surgery, but it was short-lived. The surgeons, however, continued to work together, and in 1435 the Guild of Surgeons was founded, the College of Physicians being founded later. After tracing the evolution of medicine and surgery in the succeeding centuries the orator concluded by adverting to the usefulness of the study of modern languages.

Mr. CHRISTOPHER HEATH proposed, and Mr. HENRY MORRIS seconded, a cordial vote of thanks to the orator, which was carried by acclamation, and Mr. RICHARDSON CROSS briefly replied.

The meeting was then resolved into a conversazione.

PATHOLOGICAL SOCIETY OF LONDON.

The Morphology of the Genus Streptothrix.—An Unusual Case of Intestinal Obstruction.—Case of Calcified Pericardium.—Thrombosis of the Lateral Sinus in General Tuberculosis.—Sarcoma of the Suprarenal Body.—Calculi Formed on Pubic Hairs.—Annual General Meeting.

A MEETING of this society was held on May 21st, Mr. W. WATSON CHEYNE, the President, being in the chair.

Mr. A. G. R. FOULERTON and Dr. C. PRICE-JONES communicated a paper on the Morphology and General Characteristics of the Genus Streptothrix. Cultures of 25 species, 10 of which were pathogenic, were shown. These included four new species—streptothrix luteola, streptothrix leucea, streptothrix leucea saprophytica, and streptothrix erythrea. Of these the first was pathogenic, having been isolated in pure culture from a case of acute conjunctivitis with sloughing of the cornea. It was not the same organism which Dubois St. Sevrin had described under the name of streptothrix aurea as a cause of conjunctivitis. The morphology and method of development of the various species shown was considered and Mr. Foulerton and Dr. Price-Jones pointed out the reasons for placing the streptothricheæ amongst the hyphomycetes, or mould fungi, rather than amongst the bacteria, or fission-fungi. The writers who had regarded them as highly pleomorphic fission-fungi had been misled by the examination of single species in which the true course of development was difficult to follow. An examination of a series of species left no doubt in the minds of Mr. Foulerton and Dr. Price-Jones but that the original classification of Hartz, which placed these species amongst the higher fungi, was the correct one. Out of the 10 pathogenic species examined, two, streptothrix Nocardii and streptothrix capræ, were found to be both acid-fast and alcohol-fast, whilst two, streptothrix Eppingeri and the streptothrix described by Sabrazès and Rivière, were found to be acid-fast, but the carbol-fuchsin was discharged by a subsequent washing in absolute alcohol. Lantern slides illustrating the fragmentation of the mycelium and the development of spores by segmentation were exhibited; and an exhaustive table was submitted comparing the 25 species examined by Mr. Foulerton and Dr. Price-Jones as regards their growth on gelatined on inspissated horse-serum, their diastatic action on starch, their growth on nutrient malt-agar (the best medium to grow them upon), on potato and in alkaline milk, their thermal death-point, and their staining reaction to the Ziehl-Neelsen method. No doubt but that the species of streptothrix described by Afanassiew and others in certain cases of human disease was identical with streptothrix bovis communis, which was the cause of the common actinomycosis of cattle. But many other species had been met with and these were briefly referred to. Possible sources of infection for man were to be found in cereals which were known to harbour fungi of this sort; absolute proof of infection of man from this source was, however, still wanting. Some of these fungi had been found in grass.

Dr. HUGH THURSFIELD narrated an Unusual Case of Intestinal Obstruction. The patient was a boy, aged two and a half years, who was admitted to the Hospital for Sick Children, Great Ormond-street, with symptoms of intestinal obstruction which had set in three days before admission. From birth he had had attacks of vomiting which recurred every four to six weeks. He was operated on, but without any definite obstruction being found. At the post-mortem examination the mesentery was discovered to have only its primitive short attachment to the spinal column, while the colon ran behind instead of in front of the small intestines. The anomalous conditions appeared to be capable of explanation by a reversal of the normal twist of the gut from left to right, which occurred in the process of development at a certain period of intra-uterine life.

Mr. ERNEST JONES (introduced by Dr. J. ROSE BRADFORD) exhibited a specimen of Calcified Pericardium taken from the body of a man, aged 60 years, who had died in University College Hospital in November, 1900. He had never had rheumatism, but had suffered from dropsy for 10 years. There was enormous enlargement of the præcordial area of dulness but no definite murmur to be heard. There was left hemiplegia. He died from pneumonia and at the necropsy the most noticeable feature was the presence of free spaces outside the heart, between it and the pericardium, filled with blood-clot. The walls and cavities of the ventricles were of about the normal size, but the auricles were enormously dilated and their walls thinned, especially the left. The true condition was not diagnosed during life, the case being looked upon as one of great dilatation of the heart. No cause could be suggested for the hæmorrhage into the pericardium. Mr. Jones had collected records of 58 cases of calcified pericardium. The condition seemed to be twice as common in the male; the average age was 48 years, whereas adherent pericardium was equally common in the two sexes and the average age was 38 years. There seemed to be no signs diagnostic of calcified pericardium during life. There had been no cardiac signs at all in a quarter of the cases, and the diagnosis even of adherent pericardium had only been made once in the 58 cases. The patient occasionally lived for 19 or 20 years. There was no valvular lesion at all in half the cases and it had only been slight in two-thirds of the remainder. The probable causes of the condition were discussed. Suppurative pericarditis and tubercle were often given as the chief causes, but in only 13 per cent. of these cases the lesion was probably the result of the former, and not one case could be clearly traced to tubercle. Mr. Jones was indebted to Dr. J. Rose Bradford for permission to publish the case.

Dr. J. FAWCETT exhibited a specimen of Thrombosis of the Lateral Sinus and Cerebral Veins in a case of General Tuberculosis. The patient was a boy, aged three and a half years, who died from general tuberculosis of the subacute type. There were caseous mediastinal and bronchial glands with caseous broncho pneumonia and tuberculosis of the abdominal viscera. The brain showed extensive thrombosis of the veins over the ascending frontal, parietal, and temporo-sphenoidal lobes on the right side, and the lateral sinus was also completely thrombosed as far as the jugular foramen. There was no clot in the internal jugular vein. The cerebral substance corresponding to the vascular area affected was in a condition of acute red softening with many hæmorrhages present. There was no thrombosis in any of the arteries or of the other sinuses nor any local source of infection within the cranium, such as ear disease. The extensive softening with hæmorrhages pointed to an infective origin. In most of such cases thrombosis was due to marasmus.

Dr. FAWCETT also exhibited a specimen of Sarcoma of the Right Suprarenal Body removed at the necropsy on a woman, aged 30 years. The growth measured 26 by 21 centimetres and was adherent to the under surface of the liver. Satisfactory microscopical preparations had not yet been obtained on account of the friable nature of the tumour. There were two specimens of suprarenal sarcoma in the museum of Guy's Hospital.

Dr. HUGH THURSFIELD exhibited the Left Femur from a case of Infantile Scurvy occurring in a boy, aged 13 years, hardened in formalin so as to preserve the colour.

Mr. THOMAS BRYANT exhibited several Calculi which had been formed on Pubic Hairs.

The annual general meeting was then held. Certain alterations in the rules, as recommended by the council, were put to the meeting and carried, the PRESIDENT explaining that their object was to abolish the distinction between resident and non-resident members.—The annual report, read by the SECRETARY, showed the society to be in a prosperous condition. The institution of the laboratory meetings had been a success. The future work of the society would be promoted by its division into four sections. The Secretary also read the treasurer's report, which showed a satisfactory balance at the banker's. The society had arranged to pay less rent for the use of the room for meetings.—The adoption of these reports was carried.—Sir R. DOUGLAS POWELL, Bart., proposed, and Mr. S. G. SHATTOCK seconded, a vote of thanks to the retiring officers and the council.—Mr. D'ARCY POWER proposed, and Dr. W. BULLOCH seconded, a vote of thanks to the retiring secretary, Mr. C. A. Ballance.

At the close of the ballot it was announced that the officers and council for the ensuing session, as nominated by the council, had been elected as follows:—President: Mr. W. Watson Cheyne. Vice-Presidents: Dr. E. Crookshank, Dr. W. D. Halliburton, Mr. V. A. H. Horsley, Dr. E. Klein, Dr. S. Martin, Dr. F. W. Pavy, Dr. J. F. Payne, and Mr. J. H. Targett. Treasurer: Dr. Sidney Coupland. General Secretary: Dr. J. Rose Bradford. Sectional Secretaries: Dr. H. Morley Fletcher, Mr. A. G. R. Foulerton, Dr. T. Grigor Brodie, and Dr. A. E. Garrod. Council: Dr. James Galloway, Dr. C. D. Green, Dr. H. D. Rolleston, Dr. N. Dalton, Dr. G. F. Still, Dr. T. W. P. Lawrence, Mr. D'Arcy Power, Dr. F. W. Andrewes, Dr. W. Bulloch, Dr. John McFadyean, Dr. Allan Macfadyen, Mr. H. G. Plimmer, Mr. W. C. C. Pakes, Dr. W. S. Lazarus-Barlow, Mr. W. Edmunds, Dr. E. H. Starling, Mr. C. A. Ballance, Dr. F. G. Hopkins, Dr. V. Harley, and Dr. S. G. Hedin.

LIVERPOOL MEDICAL INSTITUTION.

Perforated Gastric Ulcer.—"Malignant Polypus."—Tetanus.—Friedreich's Ataxia.—Family Muscular Atrophy.

AN ordinary meeting of this society was held on May 9th, Mr. EDGAR A. BROWNE, the President, being in the chair.

Mr. ROBERT JONES related a successful case of operation for Perforated Gastric Ulcer. The patient, a male, had an attack of hæmatemesis two and a half years previously. On Dec. 19th, 1900, whilst taking lunch, he was suddenly seized with great pain. When seen at 10 P.M. his pulse was rapid, the abdomen was slightly distended, there was an absence of liver dulness, and the patient was suffering great pain. He was removed to hospital and two hours later he was operated upon, an ulcer being found on the anterior surface of the stomach at the pylorus. The opening was closed with Lembert sutures and a piece of omentum was stitched over the suture line. Mr. Jones stated that this was his third case. In two of the cases the patients had recovered. The other patient had died on the fifteenth day from the formation of a sub-diaphragmatic abscess due to an infection of the lesser omentum, caused probably by irrigation of the abdomen.—Mr. RUSHTON PARKER said that it had happened to him also to have two early cases operated upon on the same evening as the accident and resulting in success, while in another, after three days' delay, death resulted owing to suppuration beneath the diaphragm which could not be recognised at the operation.

Mr. CHAUNCY PUZEY showed a man, aged 61 years, whose right superior maxilla he removed in January last for "Malignant Polypus" growing from the Antrum. The line of incision was Ferguson's and the result was a good instance of the very slight disfigurement which that extensive wound often leaves. Before the operation the origin of the polypoid growth, which filled the right nares (anterior and posterior), was doubtful, as there was no alteration in the shape of the jaw either in the cheek or the mouth, but there was obstruction of the lacrymal duct. The principal complaint made by the patient was that he was suffering from incessant and often agonising pain shooting up behind the eye and right forehead to the top of his head. This was readily accounted for when it was found during the operation that all the posterior wall of the antrum had disappeared, together with a considerable portion of the floor of the orbit and a portion of the ethmoidal cells, this being apparently the result of pressure (not infiltration) by the growth. The growth was reported to be "sarcoma, spindle-celled, with a considerable amount of interstitial tissue in parts, not very malignant."

Dr. D. SMART related a case of Tetanus, successfully treated by Hypodermic Injections of Carbolic Acid. The patient, a male, aged 33 years, who had been drinking heavily and lying about a stable, had a chronic ulcer on each shin which was covered with a filthy dressing. On admission to hospital he had a severe tetanic spasm, the back, the jaws, and the legs being affected. The treatment was copious liquid nourishment by means of funnel and tube, one third of a grain of morphia, and bromide and chloral every four hours, the ulcers being scraped and dressed with 1 in 40 carbolic lotion. Next day the spasms occurred every half hour, and 10 cubic centimetres of antitoxin were administered. The following day he seemed worse; 10 cubic centimetres of antitoxin were given again, but later his condition was so serious that 20 minims of a 1 in 50 solution of carbolic acid were injected and repeated every three hours, after which improvement set in. In five days he was practically well, having had 28 injections in 84 hours (in all 11½ grains of pure carbolic acid). The conclusions were: (1) that the filthy dressings of the ulcers illustrated the anaerobic nature of the tetanus bacillus; (2) that the doses of tetanus antitoxin (10 cubic centimetres given twice) were probably too small; (3) that the hypodermic injections of carbolic lotion produced neither local irritation nor carboluria; and (4) that although chloral and bromide were administered throughout the illness recovery was attributed to the use of carbolic acid.—Mr. R. W. MURRAY mentioned two cases of tetanus that had been under his care. In one the symptoms commenced 14 days after a burn of the right leg and side, the first indication of the disease being right facial paralysis. Death occurred within 48 hours. The other was that of a gardener, who cut his finger and the symptoms, which were of the subacute type, were first noticed nine days later. He was treated with anti-tetanic serum, having in all 50 cubic centimetres, and he recovered.—Dr. T. R. BRADSHAW referred to a case brought before the society eight years ago in which recovery had ensued on the administration of chloral and bromides. He doubted whether the recovery in Dr. Smart's case could be attributed to the therapeutic measures employed. The case was evidently not a severe one and had lasted some days before the injections of carbolic acid were used, and when a case had lasted a week or 10 days it commonly ended in recovery.—Mr. G. P. NEWBOLT considered that patients the subjects of acute tetanus usually died in 48 hours after the onset in spite of treatment, whether by antitoxin or carbolic acid injections. In the cases of so-called chronic tetanus the patients got better as a rule, though in many of them spasms were very severe and it was often difficult to draw the line between the acute and the chronic case.—Mr. RUSHTON PARKER classified cases of tetanus as acute and chronic The former commonly lasted no more than 24 or 48 hours; the latter a week or more, sometimes many days The period of incubation was of too uncertain a duration to rely upon as an indication of acuteness or chronicity. The mortality of acute tetanus was understood to be 100 per cent however treated, while that of chronic tetanus did not exceed 50 per cent under expectant management. If by successful treatment they could diminish the mortality to a notably lower figure in chronic tetanus, that was about all they were at present entitled to hope for. His own cases had all been acute and rapidly fatal with one exception, a boy, aged 14 years, in whom he had recognised chronic tetanus, and had injected antitoxin with, he believed, curative effect, or at least apparent relief. But in Dr. Smart's case it seemed that relief was produced by carbolic injections In Mr Parker's opinion it did not seem that "severity" of symptoms could be taken as a measure of the acuteness, as in his chronic case the severity of pain and rigidity seemed equal to anything that he had seen even in acute and fatal cases.

Dr. R CATON read a report on Three Cases of Friedreich's Ataxia in One Family. No evidence existed of antecedent nervous disease in the family and there was no history of syphilis or of excess in alcohol Ataxia, nystagmus, impairment of speech, and loss of tendon reflexes, occurred in all of the cases. There was slow tremor in two of them and lateral spinal curve, talipes equinus, and dorsal flexion of the hallux occurred in one case. None of the other symptoms characteristic of tabes were present. The disease appeared to have commenced in the three cases at the ages of 11, 14, and 17 years —Dr BRADSHAW showed a fourth case of Friedreich's ataxia in a girl, aged 16 years. There was no neuropathic family history, neither was there consanguinity in the parents. No other members of the family were affected. The symptoms began a year ago with unsteadiness in walking which had progressed. There were nystagmus, loss of knee jerk, and unsteadiness when standing which was not increased when the eyes were closed. Sensory symptoms were absent and there was no marked interference with articulation.
